LIBRARY
UNIVERSITY OF ILLINOIS
URBANA

INDEX TO VOLUME I., 1924.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.)=Leading Article or Annotation, (C.)=Correspondence, (C.M.P.)=Conduct of Medical Practice, (M.L.)=Medico-legal, (M.T.T.)=Modern Technique in Treatment, (N.I.)=New Invention, (O.)=Obituary, and (R.)=Review.*

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

Abdomen, culture of the (F. A. Hornibrook) (R.), 685
Abdominal aneurysm, case of, 233
Abdominal control, 685
Abdominal emergencies, preventable, 477
Abdominal spasm, painful, outbreak of epidemic encephalitis with, 646
Abdominal support, improved, 655
Aberdeen, joint hospital scheme, 260
Abortion, artificial, in Austria, 96; epizoötic, and Malta fever (A.), 297; in Germany, 1020; incomplete febrile, treatment of (A.), 244
Abraham, J. Johnston, tests for cure of gonorrhœa in women, 429; treatment of acute gonorrhœa in the male (M.T.T.), 1223; treatment of acute gonorrhœa in the female (M.T.T.), 1281
Abram, Prof. Hill, retirement of, 568
Abrams, Dr. Albert (A.), 146
Abrams, "electronic reactions" of (F. Howard Humphris), 176; (C.), 309; (C.), 359; (C.), 360; (C.), 415
Abrams investigation, an (A.), 191
Abt, Isaac A. (ed.), pediatrics (R.), 1109
Accidents, street, prevention of (A.), 245
Acclimatisation, 892
Account-keeping: assessment of income-tax (C.M.P.), 30
Acetonæmia and volvulus of small intestine in childhood (F. John Poynton), 1045
Acetonæmia, incidence of occurrence of, 1045
Acetone bodies, tests for, 120
Achard, Ch., Clinique Médicale de l'Hôpital Beaujon (R.), 957
Acid-base balance of blood (A.), 558
Acidosis in relation to acute rickets (Norman Burgess and A. A. Osman), 281
Ackermann, A. S. E., popular fallacies explained and corrected (R.), 528
Acoustic aid for the deaf, 1140
"Acoustique" electrical aids for the deaf, 476
Acromegaly, hyperglycæmia and glycosuria in (Arthur W. M. Ellis), 1200; (C.), 1289
Acute abdomen, malaria simulating, 986
Acute abdominal diseases, diagnosis and treatment of (Joseph Adams) (R.), 653
Adams, Dr. Alexander Maxwell, death of, 872
Adams, Joseph, diagnosis and treatment of acute abdominal diseases (R.), 653
Addison's anæmia (see Anæmia, pernicious)
Adenoid child, the, 291
Adoption of children (A.), 606
Adrenalin, idiosyncrasy to (H. E. Symes-Thompson), 743, (A.) 762
Adrenalin idiosyncrasy in relation to local anæsthesia, 743
Adrenals, function of, in relation to emotions, 378
Advertising, doctors and, 423; (C.), 464; (C.), 674
Advertising health (A.), 713
Advertising margarine: a disclaimer (C.), 416
Adwick-le-Street and Bentley-with-Arksey, M.O.H. report, 1187
Aeroplane-landing, eyesight and (A.), 348
Africa, hunters in, medical advice for (R. W. Burkitt) (R.), 266

AFRICA, SOUTH, CORRESPONDENCE FROM.—Medical Council Conference at Johannesburg, 48—Medical school for natives, 48—Responsibility for swab left in patient, 47—Transvaal, resignation of Dr. Leipoldt, 47

After-care for the tuberculous (A.), 401, 487
After-care of the cancer patient (A.), 405
After-care of tuberculous ex-Service men, 299
Air navigation and the scope of preventive medicine (C.), 309
Aircraft, protection of, from insects, 580
Alcohol and longevity (A.), 758
Alcohol, control of (A.), 36
Alcoholism and social classification (A.), 85
Alcoholism in various social classes, 109; mental states in (Bedford Pierce), 841
"Aleukia," 495
Aleukia or aplastic anæmia, associated with thrombopenia (S. C. Dyke), 1048
Alexander, F. Matthias, constructive conscious control of the individual (R.), 1077, (C.) 1288
Alimentary sepsis from the practitioner's point of view, 183
Alkali treatment, limitations of, 537
Alkalinity, human tissue, experimental and therapeutic alterations of (J. B. S. Haldane), 537, 786
Allevard-les-Bains, 1037
Allison, V. D., Fleming, Alexander and, anti-bacterial power of egg-white, 1303
Allonal, 398
Altounyan, E. H. R., serum diagnosis in Syria, 73
Alveolus, upper, myeloma of, in a child (P. B. Kittel), 900, (C.) 977
"Ambidex" nail brushes, 686
Ambulance camels, 686; cases in London (A.), 757; field, diary of a (R.), 528
Ammonium chloride, therapeutic use of, 538
Amyostatische symptomenkomplex, der (Dr. A. Bostroem) (R.), 849
Amyotrophic paralysis, post-serotherapeutic (A.), 762
Anæmia, aplastic, 1048; pernicious, internal hæmolysis in, 529; familial occurrence of (C.), 673; relationship of hæmolytic disorders to (P. N. Panton, A. G. Maitland-Jones, and George Riddoch), 529; treatment of, by excavating bone-marrow (A.), 964
Anæmia, tropical, 887
Anæsthesia and anæsthetics, discussion on, 598
Anæsthesia in dental surgery (T. D. Luke, ed. J. Stuart Ross) (R.), 754
Anæsthesia, local (A.), 1277; (H. Braun) (R.), 1006; toxic effects of, (A.), 1013; (C.), 1129; (C.), 1183; (C.), 1237
Anæsthesia, methods of, for nasal, dental, and oral operations, 1268; present position of, 1267
Anæsthetic administration, dangers during, 26
Anæsthetic mask, new, 240
Anæsthetics, a coroner on (M.L.), 252; explosion of, 723; local, toxic effects of (A.), 1013; practical (H. Edmund G. Boyle and C. Langton Hewer) (R.), 184; unusual accidents with (A.), 1014
Anaphylaxis, case of (C.), 824; pathology of (A.), 248
Anatomical abnormalities (Gordon Harrower), 285; (A.) 296,
Anatomy, human, hand atlas of (Werner Spalteholz (R.), 706
Anatomy and physiology (Jesse Feiring Williams) (R.), 447
Anderson, Grace H., Graham, Stanley G., and, the facial phenomenon in older children, 1307
Andrewes, C. H., an unexplained diazo-colour-reaction in uræmic sera, 590
Aneurysm, abdominal, case of, 233
Aneurysm needle for deep ligations, cup-and-ball (N.I.), 710
Angina pectoris (Sir James Mackenzie) (R.), 27; Jonnesco's operation for (A.), 660
Anglo-Russian medical committee, 522
Animal diseases, lessons of (A.), 1118
Ankle, fractures of, treatment of (W. A. Cochrane) (M.T.T.), 1120
Ankylostomiasis, treatment of, in Egypt, 436
Annals of medical history (R.), 186
Anopheline vectors of malaria, methods of dealing with, 24
Anophelines, a study of, 1228

NOV 14 24

560793

Anoscope and syringe for injection treatment of hæmorrhoids, 1162
Anthelmintic, a new, 398, 632
Anthelmintic work in Egypt (H. B. Day), 435
Anthology, a clinical (A.), 609
Anthrax, efficacy of disinfections, 720
Antibodies, endothelium and (A.), 910
Antidiabetic functions of pancreas and isolation of insulin (J. J. R. Macleod and F. G. Banting) (R.), 1318
Antigens, diaplyte, 68, 483; partial, in pulmonary tuberculosis, 482
Antileucocytolysins (C.), 922
Antimony in bilharziasis, 435
Anti-tuberculosis campaign in Canada, 419
Aorta, degenerative conditions in, 1004
"Apostemate," the word, 632
Apothecaries' garden at Chelsea (F. Dawtrey Drewitt) (R.), 906
Appendicitis, acute, hyperæsthesia in, 122
Appendix, three cases of new growth of (Hilda K. Whittingham), 948; nerve-supply of, 125
Appointments, weekly lists of, 56, 108, 159, 211, 262, 315, 369, 422, 472, 524, 578, 683, 783, 830, 881, 933, 984, 1036, 1088, 1137, 1192, 1242, 1294, 1342
Arc-light baths, value of (C.), 1290
Archer, Thomas Brittin (O.), 626
Argyll Robertson pupil in non-syphilitics (A.), 963; (C.), 1026
Arkwright, J. A., foot-and-mouth disease in England, present problem of, 250
Army Dental Corps, 358
Army Medical Service, 974
Arris and Gale lecture on mechanism of larynx (V. E. Negus), 987
Arsenic compounds, organic, in pulmonary tuberculosis (John Guy and G. B. Page), 845
Arsenical compounds, organic (George W. Raiziss and Joseph L. Gavron) (R.), 499
Arsenobenzol, neuro-recurrence after, 901, 1158
Arsphenamin, use of, after exposure to syphilis (A.), 914
Art exhibition by medical men, 914, 1133
Arterial elasticity in man, 1007
Arterio-sclerosis in a mesozoic crocodile, 230
Artificial respiration, 886
Aspirin in pneumonia, 8
Assam, health report from, 1022
Assessment of physical fitness (A.), 965
Assyrian medical texts (R. Campbell Thompson) (R.), 601
Asthma, tuberculin in (C.), 1027
Auenbrugger, Leopold, and percussion, 263
Aural vertigo (C.), 821; (C.), 922
Auricular beat, the (C.), 157; (C.), 204
Auricular fibrillation, treatment of, 392
Auricular fibrillation without heart failure, massive doses of digitalis in (Julius Jensen), 747
Auscultation, percussion and, history of (A.), 245; (Sir William Hale-White), 263
Australia in the war, official history of, Vol. XII. (photographic record) (R.), 394
Austria, abortion in, 96
Auto-hæmo-therapy in bacterial infections (S. G. Billington), 431; (C.), 518
Auto-infection in puerperal sepsis, 1093
Autopsies and death certification (A.), 660
Auto-pyo-therapy (C.), 50
Aviation and defective smell, 164
Axhausen, Georg, die chirurgie des anfängers (R.), 135

B

Backache (R. H. Paramore), 283
Bacteria, polymorphism in, 705
Bacterial food contamination (A.), 33
Bacterial food poisoning, reports on, 152
Bacteriology, Bergey's manual of determinative (R.), 500; colloid phenomena in (A.), 193; of dental caries, 230; popular, fighting foes too small to see (J. McFarland) (R.), 707
Bacteriophage, 1105
B. pyocyaneus infection (C.), 625; cured by vaccine treatment, 437
Bahamas, health report, 986
Bailey, Hamilton, studies in the male breast, 1258
Bainbridge, F. A., the physiology of muscular exercise (R.), 135
Baker's itch, 111
Bandages, seamless bias, 986
Bandelier, Bruno (O.), 1188
Banting, F. G., Macleod, J. J. R. and, antidiabetic function of pancreas and successful isolation of insulin, 1318
Banting Research Foundation, 827
Barbour, D. N., psycho-analysis and everyman (R.), 1320
Barker, L. T., blood pressure, cause, effect, and remedy (R.), 1160
Barker, W. H., and Brooks, Leonard, Junior Regional Geographies (R.), 850
Barnes, Francis M., introduction to study of mental disorders (R.), 706
Barnstaple, M.O.H. report, 1187
Barrett, Florence E., equal pay for equal work (C.M.P.), 1273
Barrett, Dr. W. H., death of, 946
Bartholin's gland, carcinoma of (A.), 349
Barton, E. S., how to nurse cancer patients (R.), 405
Barton, George Alexander Heaton (O.), 155
Basutoland, health report, 58
Bathing and ear disease (C.), 1081
Battle, W. H., carcinoma of breast, 1
Bayer "205" (A.), 452; and Fourneau "309," 528; composition of (A.), 663; in sleeping sickness, 356, 442, 632; in trypanosomiasis (F. K. Kleine), 384, 442; surra of horses and (A.), 406
Bayly, Hugh Wansey, venereal disease, 2nd ed. (R.), 1060
Beaton, Edwin (O.), 978
Beattie, Prof. J. M., and Peden, David, foot-and-mouth disease in rats, 221
Beatty, memorial to the late Dr. Wallace (C.), 157
Bechuanaland, health conditions in, 318
Bed, reading in (A.), 298
Bed-isolation in measles and chicken-pox (E. H. R. Harries), 491; discussion, 497
Belgium, venereal disease in, 1284
Bell, W. Blair, the influence of lead on normal and abnormal cell-growth and on certain organs, 267
Bencraft, Henry William Russell, knighthood conferred on, 36
Beneke centenary, 781; (C.), 875
Bergey's manual of determinative bacteriology (R.), 500
Beri-beri and polyneuritis, 229
Beri-beri, collected papers on (H. Fraser and A. T. Stanford) (R.), 1320; spore-forming bacterium on rice grains, 1054

BERLIN, CORRESPONDENCE FROM.—Abortion in Germany, 1020—Bacterial flora of paper money, 819—Battle of clubs, 154, 671—Bayer "205" in sleeping sickness, 356—Berlin University, statistics of, 672—Foot-and-mouth disease, isolation of virus of, 1020—German medical men in Afghanistan, 1021—Gottstein, Prof., retirement of 1021—Government reward for life-saving abolished, 672—Insurance practice in Britain and Germany compared, 1021—Malaria treatment of G.P.I., dangers of, 819—Medical practices, transfer of, 819—"*Mensæ medicæ*," 356—Plethora of medical men, 155—Prescription writing, economy in, 819—Sterilisation of the unfit, 356—Underfeeding among school-children, 155

Berlin, medical practice by foreigners in (A.), 860
Bertwistle, A. P., descriptive atlas of radiographs of bones and joints (R.), 1161
Berufsberatung, handbuch der ärtzlichen (editor, Prof. H. Lauber) (R.), 34
Besançon, 1038
Betenson, Dr. W. B., death of, 648
Betting habit, the (A.), 243
Beverages, posology of (P. L. Violle), 998
Bickersteth, Robert Alexander, 574; (O.), 625
Bickham, Warren Stone, operative surgery, Vols. I.-II. (R.), 601
Bigger, J. W., Theobald, G. W., and, a simple method of preparing hands and gloves for operation, 489, (A.) 503, (C.) 569
Bilharzia disease, treatment of (J. B. Christopherson) (M.T.T.), 1071
Bilharzial papillomatosis of the rectum (Robert V. Dolbey and Ibrahim Fahmy), 487
Bilharziasis, tartar emetic in (C.), 1130; (C.), 1184; treatment of, in Egypt, 435
Biliary cirrhosis due to manganese, experimental, 495
Billington, S. G., auto-hæmotherapy in bacterial infections, 431
Biochemistry (A.), 1009; present position and outlook (F. Gowland Hopkins), 1247
Biometry, medical (A.), 39
Birdwood, Roger Alan (O.), 105
Birmingham, cancer in, 780
Birmingham, hospital coördination in (A.), 1065
Birth injuries, discussion on, 546
Birth weight and length, effect of maternal conditions and nutrition on (M. Bruce Murray), M.R.C. Rep. (R.), 454
Births, marriages, and deaths, weekly lists of, 56, 108, 159, 212, 263, 316, 369, 422, 473, 525, 579, 631, 683, 733, 783, 830, 882, 933, 984, 1036, 1088, 1138, 1193, 1242, 1285, 1342
Births, notification of, obligations as to, 137
Bishop, Louis Faugeres, key to the electrocardiogram (R.), 1214
Bismuth cream, Bicreol brand, 32
Bismuth in interstitial keratitis (A.), 611
Bismuth therapy in syphilis, 901, 1284
Bladder diverticulum, cancer in (A.), 860
Bladder, idiopathic hypertrophy of, 655
Blair, V. P., and Ivy, R. H., essentials of oral surgery (R.), 184
Bland-Sutton, Sir John, orations and addresses (R.), 1060
Blastomyces, causing peri-onychia, 128
Blood, practical analysis of (Victor Caryl Meyers) (R.), 395
Blood chemistry, colorimetric methods: Willard Stone (R.), 135
Blood coagulometer, a clinical, 1007
Blood-compatibility of mother and child, (C.), 258; (C.), 362
Blood corpuscle, a re-discovered (A.), 457
"Blood" cysts, nature of (A.), 861
Blood-groups and opsonins (A.), 145
Blood-groups, medico-legal importance of (A.), 913
Blood, inorganic constituents of, in certain pathological conditions (O. L. V. de Wesselow), 1099
Blood pressure (L. T. Barker) (R.), 1160
Blood transfusion, 1180; in Japan (A.), 192; simple method of, 391
Blood uric acid in skin diseases (A.), 143
Bloomfield, Alice, after-results of abdominal operations for retroversion, 227
Bond, William Arthur (O.), 519
Bone: Die normale und pathologische physiologie des Knochens (Walther Müller) (R.), 754
Bone grafting, 115
Bone marrow after experimental splenectomy (C.), 102
Bones and joints, descriptive atlas of radiographs of (A. P. Bertwistle) (R.), 1161
Bonney, Victor, excision of the rectum: abdomino-vaginal as alternative to abdomino-perineal method, 592
Bootle, M.O.H.'s report, 820
Borradaile, L. A., manual of elementary zoology, 4th ed.; elementary zoology for medical students (R.), 290
Bosc, S. R., spore-forming bacterium on rice-grains used by families suffering from beri-beri and epidemic dropsy, 1054
Bostroem, Dr. A., der amyostatische symptomenkomplex (R.), 849
Botulism, the Loch Maree outbreak, 152
Bovet, Pierre: the fighting instinct (R.), 136
Boxing, primary dislocation due to (C.), 726
Boyle, H. Edmund G., and Hewer, C. Langton, practical anæsthetics (R.), 184
Brackenbury, Dr. H. B., B.M.A. gold medal awarded to, 879
Brackenbury, Dr., proposed honour for, 402; (C.), 414; (C.), 726
Bradley, O. Charnock, topographical anatomy of head and neck of horse (R.), 1215
Bragg, Sir W., X rays and crystal structure (R.), 602
Brain, certain minor injuries of the (Wilfred Trotter), 935; vulnerability of, individual and racial, 937
Bramwell, Dr. Byrom, baronetcy conferred on, 36

Brand, Alex. Theodore, and Keith, John Robert, clinical memoranda for general practitioners (R.), 184
Braun, H., local anæsthesia (transl. Malcolm L. Harris) (R.), 1006
Bread, standard and wholemeal, nutritive value of, 1178
Breast, cancer of, surgical treatment of, 1074; carcinoma of (W. H. Battle), 1; carcinoma of, unusual cutaneous metastases in (W. D. Newcomb), 1056; male, studies in the (Hamilton Bailey), 1258
Breast-milk feeding (Catherine Chisholm), 425
Brides-les-Bains and Salins Moutiers, 1037
Briggs, L. Vernon, occupation versus restraint (R.), 551; where does mental hygiene begin? 526
Brighton intercepting sewer, 214
British Columbia, goitre in (A.), 1221
British Empire cancer campaign, 981
British Empire Exhibition: medical and sanitary administration, 1126; health in the tropics, 864, 916, 1022; Ministry of Health and, 729
British Empire Leprosy Relief Association, meeting of, 306
British Honduras, public health in, 580
British Hospitals Association, annual conference, 1331
British Medical Association, annual meeting, 1924 (A.), 350
British Medical Association, scholarships and grants, 678
British Science Guild, 472
Broadbent, Walter, pneumonia and its complications, 6
Broadcasting heart sounds (A.), 861
Brock, A. J., health and conduct (R.), 81
Bronchi, foreign bodies in the (Thomas McCrae), 735, 787, 838; (A.), 858
Bronchitis, seasonable advice on (A.), 90
Bronchomoniliasis, investigation into (A.), 714
Broncho-pneumonia, 6
Bronchoscope, in diagnosis and treatment of chest diseases, 599
Brooks, Leonard, Barker, W. H., and, Junior Regional Geographies (R.), 850
Brooks, H. T., diagnostic methods (R)., 134
Brophy, Prof. T. W., cleft lip and palate (R.), 237
Brown, Lawrason, rules for recovery from tuberculosis (R.), 340
Brown, W. Langdon, types of glycosuria and their treatment, 59
Brunei, health report from, 1022, 1296
Brussels Medical Congress, 1083
Bryce, T. H., "Myology" in Quain's Elements of Anatomy (R.), 1319
Brydson, J. M., Poynton, F. John, and Higgins, T. Twistington, present position of treatment of hypertrophic pyloric stenosis, 215
Buchanan, Sir Walter, death of, 670

Bucharest, Correspondence from.—Difficulties of country practice in Bessarabia, 919—Gastric disorders and diabetes, 920—Infantile mortality in Transylvania, rise of, 920—Tuberculosis exhibition in Bucharest, 920—Workmen's Insurance System, improvement of, 919

Buckle, P., Wardle, R. A., and, principles of insect control (R.), 88

Budapest, Correspondence from.—Ectopic gestation, ætiology of, 46—Examinations in medical faculty, 47—Milk injections in general paralysis, 1231—Mortality-rate in Hungary, increased, 46—Soap inunction for lung diseases, 1231

Bull, Dr. H. A., death of, 980
Bürger, Max, Pathologisch-physiologische propädeutik (R.), 905

Goulstonian Lectures

ON SOME

WASTING DISORDERS OF EARLY INFANCY.

Delivered before the Royal College of Physicians of London

BY LEONARD G. PARSONS, M.D., F.R.C.P.,
ASSISTANT PHYSICIAN, GENERAL HOSPITAL; PHYSICIAN TO BIRMINGHAM AND MIDLAND HOSPITAL FOR SICK CHILDREN; PHYSICIAN TO THE MUNICIPAL INFANTS HOSPITAL, BIRMINGHAM.

LECTURE I.

Delivered on March 25th, 1924.

THE subject which I wish to bring to your notice is lacking in general interest and by many regarded as threadbare, but although much has been written on the subject of the wasting disorders of childhood, its problems are far from being completely solved, and the death-rate from these disorders remains very high. Dr. Goulston, in bequeathing by his will £200 to the College of Physicians to purchase a rent charge for the maintenance of an annual lecture stipulated, amongst other conditions, that if possible a dead body should be procured, and in the deed conveying the rent charge to the College it is stated that the dead body should be dissected as the President and Elects should think necessary for the diseases to be treated of. Unfortunately there would be little difficulty in procuring the dead body of a child who had suffered from a wasting disorder, but in the majority of the cases which I wish to discuss the dissection of the body would yield very little information about the diseases treated of.

The group of wasting disorders which I have studied is made up of those cases which, when seen by the physician, frequently prompt the question: "Is this patient suffering from pyloric stenosis"? The clinical picture is that of a wasted infant whose age can be measured in weeks rather than in months, and whose history is that, although normal at birth, the baby has later failed to put on weight normally; it has wasted, and probably has suffered from vomiting, and in many cases also from constipation or diarrhœa. As far as possible I have limited my investigations to infants under three months, but some have been made upon infants up to six months of age. The period of life chosen is that of *la première enfance* of French writers, and almost exactly corresponds with the age-incidence of the cases of athrepsia described by Parrot.

The subject naturally divides itself into two main subdivisions—simple atrophy or marasmus, and infantile pyloric stenosis—although it has not been found advantageous, particularly in chemical investigations, rigidly to separate the consideration of the two groups.

SIMPLE ATROPHY OR MARASMUS.

I will deal first with simple (or infantile) atrophy or marasmus (athrepsia, severe infantile malnutrition, advanced nutritional disorders of infancy, &c.). On clinical grounds only it is quite impossible to say at what point in its downward course a wasting infant becomes an atrophic one. Talbot[1] has shown that there is no appreciable change in the metabolism of these infants until there is a loss of 20 per cent. of the body-weight. I have therefore adopted as a working rule that an infant can be regarded as suffering from simple atrophy if the body-weight is less than 80 per cent. of the expected body-weight for its age, and if there is no other evidence of disease. To come to any conclusions as to the cause of atrophy it is essential to review at considerable length the literature on the subject; to examine carefully both the theories put forward and the criticisms of them, and in some instances to attempt to prove or disprove some of the experimental data on which these theories are based.

Literature.

In this review of the literature I have briefly indicated the view held by older writers. The honour, if it be such, of introducing the term marasmus into medicine is given to Soranio, a physician of Aragon, who, writing on this subject in the year 1600, states that the expression "infantile atrophy" was used in Greek medicine. A few years previously (1583) Hieronymus Mercurialis, an Italian physician, and a teacher in the schools of Padua and Bologna, published a treatise, "De Morbis Puerorum," in which, according to Marfan,[2] infantile atrophy is described under the term Macies, and the statement made that the condition was called by the Greeks *ισχνοτης, λεπτοτης*, and by the Romans macies, macilentia, gracilitas, tenuitas, macritudo.

The earliest reference to this disorder by any English writer that I have been able to find is in a small book published a few years after the Goulstonian lectures were founded. This book bears the title:—

> "A Treatise of the Diseases of Children with their Causes, Signs, Prognosticks and Cures, for the benefit of such as do not understand the Latine Tongue, and very useful for all such as are Householders and have Children. By Robert Pemell, Practitioner in Physick at Cranebrooke in Kent May the 29 1653."

The book contains a chapter headed Of the Consumption or Leaness of the Rickets. Pemell dismisses the "leaness of the rickets" by saying that a full description of it has recently been published by three London doctors, but he deals at greater length with the consumption; thus he says:—

> "Children do many times wax lean without any manifest cause, and although they suck much or feed well yet they are not therewith nourished. Now the causes are many: as the corruption of the milk for being either too hot or too cold, it turns into ill humours and so hinders the breeding of good blood; or it may come for want of suck, from whence we see many times that when a child consumes and pines away with sucking one nurse, if it sucks another it soon thrives and grows . . . If the child consume for want of milk or a good nurse this may be cured by getting a better nurse . . . The consumption in most children is dangerous if it be not taken in time and kills many." His treatment is refreshingly simple. "If the fault be in the milk that must be rectified by good dyet of the Nurse, or if that do not help, then the Nurse is to be changed."

A few years later (1659) appeared "De Morbis Puerorum" by James Primrose. This book contained a description of infantile atrophy under the heading Macies, and some of the statements contained therein suggest that he was not unfamiliar with Pemell's book. Another book of about the same period, on the Diseases of Children, was "habited in English," as the author puts it, at "Oundle in Northamptonshire" in June, 1662. I cannot give the author's name, because in the only copy I have seen the title-page of the book is missing, and in a dedicatory letter to Sir Robert Boyle the writer signs only his initials "J. S." Under the heading Of the Consumption, he says, "A consumption is called leaness, gracility and tenuity." He describes various conditions, but one of them is undoubtedly marasmus, thus:—

> "In children it is caused for the most part by the defect of nourishment, being either too little or vitious, and unuseful, proceeding from the fault of the milk." He suggests other ætiological factors—e.g., "It is also conceived that children by reason of the softness and tenderness of their body, grow lean and consume by fascination, proceeding from their touching unhealthy bodies, or the unwholesome vapours out of the eyes or mouthes of women not well, which truly is not fascination, for witchcraft is rather the work of the devil than by any power of the sages."

He gives Mercurialis and Primrose in his list of authorities, and the above quotation savours as much of Primrose as some of Primrose's statements savour of Pemell.

Eighteenth-Century Conceptions.

In 1689 Walter Harris published his book, " De Morbis Acutis Infantum." Harris was Lumleian lecturer from 1710 until his death in 1732, and his book appears to have become the standard work on children's disease in this country for many years, the last edition being part of Martyn's " A Full View of all the Diseases of Children," published in 1742. I have been unable to find any reference to marasmus in this work, although he describes a condition which he calls " atrophia verminosa."

A very good description of infantile atrophy is given by Dr. John Astruc in his " Treatise on all the Diseases Incident to Children," published in England in 1746. The chapter in which he describes the condition is headed, Of the Extenuation or Decay of Children. About a hundred years after Harris wrote his book, Michael Underwood published his " Treatise on the Diseases of Children." This book ran through many editions from 1784 to 1827, and succeeded that of Harris as the standard text-book. Like many other authors of this period Underwood confused tuberculous peritonitis with marasmus. When writing of " a confirmed hectic fever and marasmus, or a wasting of the whole body, called by some writers atrophia lactentium," he describes enlargement and suppuration of the mesenteric glands, but he clearly recognises the condition thus:

> " There is indeed an atrophy or universal decay in infants for want of the breast, or from the unsuitableness of it (which is the true atrophia lactentium), or of whatever else may be the child's ordinary food, but this is not usually attended with fever. . . . Harris recounts some remarkable recoveries in what he calls the atrophia verminosa (or worm hectic), . . . but I have seen none so marvellous as in the atrophic dententium or tooth atrophy."

In another passage he states that macies of ancient writers is " a true atrophy or marasmus."

In 1830 Dr. John Darwell, physician to the General Hospital, Birmingham, wrote a small book having the title " Plain Instructions for the Management of Infants with Practical Observations on the Disorders Incident to Children." In an article on Marasmus he says:—

> " This term which in its original significance meant nothing more than emaciation we now understand as a general expression for infantile fever. It is almost always the consequence of improper diet or regimen, or is a sequela of the exanthematous diseases."

He then proceeds to give post-mortem findings, which are those of tuberculous peritonitis and general tuberculosis. This may be taken as representing general opinion in this country, until Dr. Charles West's " Lectures on the Diseases of Infancy and Childhood," first published in book form in 1848. In these lectures Dr. West clearly differentiates infantile atrophy as a nutritional disorder, although stating that it may occur in a child who is weakened by previous disease or the subject of general tuberculous disease. He shows how insufficient and unsuitable food produces the condition.

> " Death takes place from starvation; its approach indeed having been slower, but the suffering which preceded it not therefore less, than if all food had been withheld."

In his book on the " Wasting Diseases of Children," first edition published 1868, under the heading of Simple Atrophy, Eustace Smith also well describes the clinical picture and obviously regards the condition as a " vice of nutrition." The same view of some cases was, of course, taken by Parrot in 1875.

The frequent occurrence of diarrhœa and vomiting in these children naturally led to a great deal of attention being paid to the alimentary canal, and attempts were made to classify wasting disorders on a basis of morbid anatomy. In 1879 Bouchut[3] criticised his fellow countryman Parrot very adversely for introducing the new name " athrepsia " into science, and stated categorically " athrepsia is enterocolitis." There is little reference to atrophy and marasmus in many text-books of diseases of children published about this time. Indeed, in some these terms do not appear, but many pages are devoted to acute and chronic gastritis, enteritis, gastro-enteritis, &c. The morbid anatomy theory reached its zenith in the Vienna School under Wiederhofer in 1880, and in Germany under Baginsky in 1884. The theory, however, failed when it was found that there were not any constant lesions, and that many of the appearances found were due to post-mortem changes. The unsatisfying nature of post-mortem examinations is well known to all who have performed autopsies in these cases.

A little later, in 1885, Escherich, in Vienna, investigated the bacteriology of the intestine and its contents under normal and pathological conditions. Although a bacteriological explanation of atrophy was not given, an explanation of the often associated diarrhœa was advanced, and he established the fact that the type of bacteria in the intestine depended on the kind of food given. From this time until the beginning of the twentieth century, most pediatrists seem to have halted between Charles West's and Eustace Smith's view that atrophy was due to starvation, and the view that there were morbid changes in the alimentary tract, which were the cause of atrophy. Not a few indeed seem to have tried to hold both views at the same time. Eustace Smith regarded the starvation as due to insufficient food, and also to unsuitable food, and he thought that difficulty in digesting protein was the cause of atrophy occurring in children who were fed on cow's milk. This doctrine of the harmfulness of protein of cow's milk, first enunciated by Biedert in 1869, had a considerable vogue, and, indeed, until recent times the presence of curds in the stools was regarded as due to undigested protein. This theory was never seriously challenged until the researches of Czerny and his colleagues.

The Work of Czerny.

Since the beginning of the present century a great amount of research work on nutritional disorders has been carried out by German workers, particularly by Czerny and by Finkelstein. According to Czerny[4] atrophy is not a disease per se but a disturbance in growth and in general nutrition, which is the result of nutritional disturbances, or of infective processes or both. As a result of these conditions infants do not invariably become atrophic; the reason some become atrophic and others do not is due to a constitutional anomaly. Children who do become atrophic are either suffering from the " exudative diathesis," or are the children of " neuropathic and psychopathic parents," and show extreme nervous irritability of the intestinal tract, or are children with the " hydriopic " constitution—i.e., children who show differences in salt and water retention from normal children.

Czerny's classification is as follows:—

1. Disturbances from food: (*a*) Milchnährschaden; (*b*) mehlnährschaden; (*c*) infantile scurvy.
2. Disturbances from infectious processes: (*a*) Acute disturbances; (*b*) enteral infections; (*c*) parenteral infections.
3. Disturbances from constitutional anomalies: (*a*) Exudative diathesis; (*b*) rickets; (*c*) anæmia; (*d*) neuropathic constitution.
4. Disturbances produced by congenital malformation.

The two important food disturbances which concern us are what he describes as Milchnährschaden and Mehlnährschaden.

Milchnährschaden.—This disturbance is due to over-feeding with milk, and the particular factor causing the injury is the fat in the milk; it therefore may be called Fettnährschaden. The clinical characteristics of this over-feeding with fat are failure to gain weight, constipation, with passage of pale dry crumbly soap stools, pallor, and flabbiness. Czerny's[4] view in 1912, five years after the appearance of his text book on infant nutrition, was expressed as follows:—

> " At the present time only so much can be said in regard to the food components, that it is the fat that must be restricted in the treatment of atrophy, and that the place of this must be taken by carbohydrates."

He did not believe in the use of cream in infant feeding.

Mehlnährschaden.—This disturbance is due to feeding on a diet containing too much carbohydrate (frequently starch). Such a diet not infrequently is deficient in fat and protein—e.g., a weak sweetened condensed milk mixture. The baby is markedly wasted; the stools are often frequent, usually acid, green, and watery, with a variable amount of mucus and small whitish curd masses. Occasionally the wasting is masked by œdema (hypertrophic form).

Protein, according to Czerny, never causes any upset; he does not admit any such thing as "protein injury." The curds found in infants' stools are nearly always fat and very rarely protein curds, and the factor in the production of atrophy is the difficulty in dealing with fat. He assumes that these children have a low assimilative power for fat, and as a result of fermentation and digestion fatty acids are formed in excess in the intestinal tract. To neutralise these fatty acids, alkalies are taken from the tissues and excreted into the intestine and lost in the stool. In constipation with soap stools, calcium, and in diarrhœa, potassium and sodium are thus excreted. Demineralisation of the body is the essential cause of atrophy.

> "On account of this mineral loss it is assumed that the cell structure and tissue composition is altered, and that if a sufficient loss takes place, the normal cell function will be so disturbed that the building up of new tissue is impossible, even if the processes in the intestinal tract are restored to normal."[illegible]

This theory was based on results obtained by Keller and Steinitz. Keller[6] in 1897 found a considerable increase in the urinary ammonia in 10 out of 11 infants suffering from acute and chronic gastro-intestinal disturbances, and in 1903 Steinitz[7] found that the urinary ammonia was increased by giving a large amount of fat in the food, at the same time there was an increased loss of alkali by the intestine, and a corresponding diminished loss in the urine. Both this experimental work and Czerny's theory have been criticised considerably, and the conclusions refuted by Pfaundler,[8] Meyer and Langstein,[9] and Utheim.[5]

The latter observer found that, although there is a high excretion of ammonia in the urine, it is proportionate to the amount of organic acids in the urine, which acids she found occurred in atrophic infants, and infants suffering from acute diarrhœa. With a great increase in the fat of the diet there is, however, only a small increase in the excretion of organic acid and ammonia, and she assumes that the source of the organic acids is a disordered metabolism of the body cells.

Observations made by Miss Hickmans and myself, to which I refer later, agree with those of Utheim, that increase in the amount of fat in the diet produces little increase in the ammonia, and also agree with Holt, Courtney and Fales,[10] and with Hutchison,[11] that many atrophic infants do not have a low assimilative power for fat. Czerny's work was, however, of the very greatest importance because, for the first time, he emphasised the importance of the consideration of the baby as a whole, and not simply of his food or his alimentary canal. The other great advance made by him was the demonstration of the harmlessness of protein.

The Work of Finkelstein.

Finkelstein published a classification of nutritional disorders in his text-book in 1912, which has had a considerable vogue on the Continent and in America, and has been adopted to some extent in this country (John Thomson, Dingwall-Fordyce). As will be seen it is largely a clinical classification. With Czerny, fat was the factor, but according to Finkelstein the sugar and salts are to blame. He based this view largely on the whey exchange experiments of Meyer.[12] In these experiments Meyer showed that when curd of cows' milk was mixed with whey of human milk the mixture was well tolerated, whereas when curd of human milk was mixed with whey of cows' milk the mixture was badly tolerated. These experiments, which were only few in number, have been repeated and disproved by Lichtenstein and Lindberg.[13]

According to Finkelstein the whey salts may injure the intestinal mucosa and interfere with its activity by decreasing the normal secretion, depressing the antibacterial function of the cells, and thus allowing the growth of bacteria which produce sugar fermentation. The injured mucous membrane allows the passage of harmful substances, lactose and salts into the circulation, and is itself liable to bacterial infection. The somewhat zigzag character of the weight chart in bottle-fed babies he regarded as due to variations in the salt content of the whey. He found[26] that the giving of 100 c.cm. of 12·5 per cent. lactose solutions to infants with intestinal disorders produced fever and nutritional disturbances. Other sugar and salts produced the same results, as also did lactose and salt when given intravenously. He also found that the giving of tea, or even water alone, caused the fever to disappear entirely. The fever that occurs in alimentary intoxication he regards therefore as "salt" and "sugar fever," and in his opinion it is due to injury to cells by the physico-chemical effect of the sugar or salt. In his view, the rapid loss of weight in atrophy can only be explained by a pathological loss of water. He assumes that the water combining power of the different cells of the body has been lost, and that as the result of the lack of retention of water there is a lack of retention of nitrogen and alkali.

Balcar, Sansum, and Woodyatt,[14] in examining Finkelstein's results, point out that the solutions used by him were strongly hypertonic, and quote their own experiments, which show that hypertonic solutions of crystalloids, which do not burn in the body (sodium chloride, sodium bicarbonate solutions were used), cause fever, diuresis, and dehydration, whilst isotonic solutions do not cause any of these symptoms. These observers showed that when sugar was injected intravenously, sufficiently in excess of the tolerance limit to produce marked glycosuria and diuresis, and when the rate of water administration was less than the rate of diuresis, for a period long enough to cause the loss of a certain weight by dehydration, fever was produced. They also found, as Finkelstein did, that the fever subsided when additional water was given. They point out that in cases where lactose was used every gram of lactose was recoverable unchanged from the urine, and they conclude that "sugar and salt fever" in infants is caused by dehydration and does not arise from injuries to cells.

In pursuance of his view, that the whey salts and sugar fermentation are the factors in nutritional disturbances, Finkelstein devised a special milk modification to combat this fermentation. This modification is the well known protein milk, which has a high protein, but a low sugar content. Like Czerny he also stressed the importance of the baby: "It is the sick baby we have to study, not the diseased bowel." His classification is based on the study of the weight chart.

Bilanzstörung.—In Bilanzstörung (disturbance of balance—failure to gain) the previously normal chart with a steady rise is replaced by one showing a straight line. This is the type of case described by Czerny as Milchnährschaden; in it there is diminished tolerance for fat, due, according to Finkelstein, to derangement of the relations of metabolism of carbohydrates to the fat. He aims at bringing about the normal fermentation in the bowel and the production of acid instead of alkaline soapy stools. He does so by reducing the amount of milk and adding cane sugar, maltose or starch.

Dyspepsia.—The weight curve turns slowly downwards, but there is no great loss of weight; it is the milder form of sugar fermentation, the commencement of diminished tolerance for carbohydrate. The children are fretful, and there may be slight attacks of diarrhœa. Less fermentable carbohydrates, like dextrimaltose, may be tolerated, but in the worst cases Finkelstein advised using his protein milk. If this condition does not improve the infant passes into one of the two following categories, which of the two may depend on the food; if the food contains much sugar and little fat, the tendency is to intoxication; if little sugar and more or less plentiful fat, the tendency is towards decomposition.

Alimentary Decomposition.—The weight chart shows a slow, steady fall, the condition being that of marasmus or atrophy.

Alimentary Intoxication.—Here the fall is rapid and accompanied by considerable diarrhœa, an irregular temperature, respiratory and cerebral disturbance; in its worst form this is cholerine, or cholera infantum. The condition is not due to a bacterial infection, but due, as previously stated, to the passage of whey salts through the unhealthy mucous membrane into the general circulation.

Recent Work in Britain and America.

Within recent years a great amount of work on metabolism in atrophic infants and the pathogenesis of infantile atrophy has been carried out in America. I would mention particularly L. E. Holt[*] and his co-workers, Marriott, Utheim, Morse, Talbot, &c. Important contributions have also been made by the Glasgow school, in particular by Fleming, Hutchison, Guy, and Telfer.

According to Marriott,[15] atrophy is essentially the result of partial starvation, continued for long periods of time. There is a negative mineral salt balance, and in fully developed cases of atrophy there may also be a negative nitrogen balance, showing that there is destruction of the body tissues.

> "There is diminished functional capacity of the body to oxidise organic material, and the basal energy metabolism of athreptic infants is often high as compared with those who are normal. The destruction of body substance is not confined to the solid portions of the organism, but affects the blood as well. There is a diminution in blood protein, a destruction of blood corpuscles, and a decrease in the total blood volume, resulting in a diminished blood flow, which brings about a lowering of the functional capacity of all parts of the body. When the blood flow is increased there is a return of normal function."

The well-known clinical fact, that atrophic infants may have a stationary weight for a long period, despite a fairly large intake of fluid, is probably due to this being a "period of repair," during which the functional capacity of the body for utilising food is returning. From animal experiments it would appear that the restoration of blood volume is occurring during this period.

Marriott believes that one of the chief reasons why atrophy develops on cow's milk feeding, and not on breast milk, lies in the different buffer values of the two milks. There is little difference between their acidity value. According to Clark and Lubs,[16] pH for human milk is 7·0 to 7·2, and for cow's milk 6·6 to 6·8, but the alkali reserve (buffer value) of cow's milk is much greater, for it takes three to six times the amount of added decinormal hydrochloric acid to bring cow's milk up to the same acidity as breast milk, to which a certain quantity of decinormal hydrochloric acid has been added. The buffer value of cow's milk may be lowered by diluting with water, adding carbohydrate, or by artificially souring the milk by lactic acid organisms, or by the addition of hydrochloric acid. Protein milk also has a lower buffer value. Marriott's classification is as follows:—

Acute conditions: (1) Acute diarrhœa; (2) anhydræmia.
Chronic conditions: (1) Hypothrepsia; (2) athrepsia.

In a comprehensive series of papers on infantile atrophy, Nobécourt[17] introduces a simple classification. He recognises two clinical syndromes, hypotrophy and cachexia. Each of the two syndromes is subdivided into (1) essential or protopathic, and (2) secondary or symptomatic. The ætiological factors in his essential group are the health of the mother during pregnancy, her previous medical history and habits, position in social scale, &c., and also what Czerny has described as the constitutional factor; the ætiological factors of his symptomatic group are the infections, vomiting, gastro-intestinal infections, and defective feeding. This last factor includes unsatisfactory food, under-feeding, and over-feeding. Marfan[illegible] also adopts a similar simple classification. He divides infantile atrophy into hypothrepsia and athrepsia, and says that the cause of these conditions can be classified under three heads: (1) defective food; (2) affections of the digestive tract; and (3) infections. At the present time, general opinion seems to be divided between the views of those who, like Nobécourt and Marfan, adopt a simple clinical classification, and the views of Finkelstein and Czerny, with the adoption of Finkelstein's classification rather than Czerny's.

I think it is a fair statement to make that the larger body of opinion favours the views of the former group. The experimental evidence on which many of Finkelstein's and Czerny's views have been based have, as stated previously, been seriously challenged. Actually in practice many of the cases met with cannot, in my opinion, be classified into Czerny's groups, although carbohydrate indigestion not infrequently presents symptoms similar to those described by him under the heading of Mehlnährschaden. It is quite true that, using the weight chart as a basis of classification, it can be divided up as Finkelstein has shown, but the associated clinical characteristics described by him do not always manifest themselves.

There can be no doubt, I think, that carbohydrate and fat "intolerance" or indigestion do occur, and that such groups can be separated at times, but they are not a sufficient explanation of all the simple atrophies of infancy. I think, also, that a case, whilst still atrophic, may show carbohydrate indigestion at one time and fat indigestion at another, or even a combination of both.

I hesitate to add another to the already long list of classifications, and a sentence from a recent review on one of the leading text-books of children's diseases comes forcibly to my memory:—

> "Disease of the gastro-intestinal tract is an open field; his classification will not please many more people than the author."

Personal Classification.—My classification is not very different from some of those I have quoted, but it has enabled me to label my cases. I do not differentiate between degrees of atrophy, because there can be no strict dividing line between moderate and severe atrophy, but before a child is considered atrophic it must be more than 20 per cent. under the expected weight for a child of that age.

1. Simple atrophy.
2. Simple atrophy with dyspepsia: (*a*) diarrhœa and vomiting; (*b*) fat indigestion; (*c*) carbohydrate indigestion; (*d*) protein indigestion; (*e*) pylorospasm.
3. Simple atrophy from deprivation (avitamoses): (1) absence of fat (dystrophia alipogenetica), frequently also associated with excess of carbohydrate (dystrophia amylogenetica) and often insufficient protein; (2) absence of antiscorbutic and antineuritic vitamins.
4. Atrophy associated with other diseases or infections. Pyloric stenosis and other deformities. Pyelitis, otitis media, syphilis, tubercle, broncho-pneumonia, acute epidemic diarrhœa, &c.

Ætiology.

To an even greater degree than rheumatism or tuberculosis infantile atrophy is a "social disease," and cases seen in hospital practice far outnumber those seen in private practice. This is, of course, a widely recognised fact, but it is very well demonstrated by consideration of the geographical distribution of fatal cases throughout the city of Birmingham. This city has a configuration not unlike that of Ireland, and the municipal wards can be divided into three groups: a central group, most densely populated and containing the largest number of slums and back-to-back houses, an outer group of wards which comprises the outlying suburbs, the least densely populated part of the city, and having many large open spaces, and a middle group of wards intermediate in type. In the years 1912–16 the infantile mortality-rate for "atrophy, debility and marasmus" for the whole city was 16·88 per 1000 births; the rate for the central group of wards was two and a half times the rate for the outer groups, the figure being 25·57 and 10·05 respectively, whilst for the middle groups of wards it was 13·72 per 1000 births. The heading "atrophy, debility, and marasmus" probably includes cases that should not be included under these headings; nevertheless, the figures do give a very good idea of the distribution of infantile atrophy, and show that where poverty and squalor exist atrophy is much more common than where children are brought up under better conditions. In general, the ætiological factors concerned in the prevention of atrophy are well known, but to enable my cases to be compared with those of other writers I have analysed these factors in 100 cases, under the age of 6 months, admitted into the municipal infants' hospital during the period 1920–24.

---

[*] It is with very great regret that I have read of the recent death of Dr. Holt in China. His name and work are freely quoted in these lectures, and I would like to express my admiration of him and of the quality of his work. He was, indeed, one of the greatest pædiatricians in the world and in common with his own countrymen we shall miss him sorely.

Prenatal Factors.—Only eight of the mothers had followed any occupation other than that of housework during the period of pregnancy. Thirty-two, however, gave a history of previous ill-health, 11 were said to have suffered from "anæmia," and four from "debility," four from "rheumatism," two from pulmonary tuberculosis, two from bronchitis, three from "fits," and one each from heart disease, kidney disease, sarcoma, uterine hæmorrhage, abscess of uterus, and vaginal discharge. One mother died from tuberculous meningitis 14 days after the birth of the baby. Of the fathers, five gave a history of pulmonary tuberculosis, and one of mental disease. In the family history of the patient there had been in five families deaths from marasmus; in five families deaths from "fits"; stillbirths had also occurred in five families and miscarriages in 11. Of the babies 12 were twins; in most cases both twins were admitted to hospital; in other cases one twin was atrophic and the other a normal child, although fed in the same manner. One child of triplets was admitted; three only were illegitimate children. The place in the family is an interesting point; 68 per cent. of the cases were either first, second, or third in the family, the figures for each year being practically identical.

Feeding.—Two cases only had been fed entirely on the breast, but a considerable portion had been partially breast-fed. The number of completely artificially fed babies was 19. In the cases where artificial feeding had been given either throughout life, or to supplement or replace the breast, 34 had been fed on one artificial food only, 30 on two, and 21 on three different foods. Smaller numbers only had received more than three different forms. Further analysis of the feeding presents other points of interest. The choice of type of food in children fed on one and two forms of artificial food are here tabulated:—

	One food.	Two foods.		One food.	Two foods.
Cow's milk ..	20	27	Nestlé's ..	1	11
Glaxo	8	12	Cow and Gate	1	7
Trufood	2	4	Various ..	—	6
Allenburys ..	2	3			

From the literature it would appear that machine-skimmed sweetened condensed milk is a much more important ætiological factor in the United States and on the Continent than in Birmingham, but in estimating the value of the preceding tables it should be noted that in nearly every case the infant was sent into hospital from an infant welfare centre, and that, therefore, cow's milk and the dried milks are more likely to have been used than if the parents of the children had not sought advice.

A history of diarrhœa was given in 19 cases, and of vomiting in 72, in 54 of which vomiting was said to have been of frequent occurrence; constipation occurred in 46 cases. After admission vomiting occurred in 40 cases, and diarrhœa in 27 cases; a larger number than this, however, suffered from looseness of the bowels.

THE METABOLISM OF FATS IN INFANTILE ATROPHY AND FAT INDIGESTION.

The obvious loss of fat by atrophic children, the description of Milchnährschaden by Czerny and his colleagues and their insistence on the importance of "fat injury," have led to much research on the digestion and absorption of fats in these children. Amongst the most important contributions to the subject of fat metabolism in infants I would again mention Hutchison working at Glasgow, Holt, Courtney and Fales at New York, and Utheim at St. Louis. The suggestion has been made within the last year or two that fat digestion in pyloric stenosis is defective.[18] This point has been discussed and disproved in a recent paper by Barling and myself.[19] I do not know of any observations on fat absorption in pyloric stenosis, but if Marriott's view that "athrepsia is essentially starvation" be correct, then metabolism experiments should yield similar results in atrophy and in pyloric stenosis, in which the wasting is unquestionably due to starvation.

This consideration—together with the fact that the work of these investigators would be even more valuable if confirmatory results could be obtained by what I think are more rigid methods—determined me to carry out a series of metabolism experiments. Utheim [5] examined the fat absorption in 13 atrophic infants on 20 different occasions. In 11 of the experiments the period for which the case remained under observation was five days. In four experiments the period was four days. In the other five experiments the period was two days or less. It is better, I think, to delete these five experiments in arriving at the final result. She does not say how the fat intake was estimated.

Hutchison,[11] likewise, does not give any information as to how the fat intake was estimated, nor does he say if the figures obtained were from one 24-hour specimen nor whether the experiment was carried out over a period of days. He examined 22 normal and 22 athreptic infants; the ages of the children are not stated. The most extensive series of experiments, however, are those by Holt, Courtney, and Fales.[10] They examined breast- and artificially-fed children. In the series of children fed on modifications of cow's milk, 128 specimens of fæces were examined from 77 infants, whose ages ranged from 2 to 18 months; 53 of these cases were infants under the age of 6 months, and therefore more strictly comparable with my series. Except for the cases having diarrhœa at the time of the experiments, the greater number were not ill, although the digestion of some was not normal and some subsequently developed diarrhœa. None of my cases at the time of observation was suffering from severe diarrhœa, and therefore I propose to eliminate that group of cases, when comparing them with my own. The actual figures obtained by these workers I will give later on. In three quarters of the cases the stools examined were collected for a definite period; the actual length of time is not stated, but in a letter sent to Findlay, Paton, and Sharpe [20] Holt says:

> "In most of the cases the values reported are averages for two or three days, frequently for longer periods. The values for infants are mostly for three and four day periods . . ."

In fat metabolism experiments it would seem advisable as far as possible that the following conditions should be observed: (1) That the actual fat intake of the food should be known; (2) that the stools examined should be those resulting from this food; (3) That the stools should be examined for a considerable period, at least five days.

The time occupied by food passing through the alimentary canal in infants is variable; it varies to some extent with the character of the food; it obviously varies according to the presence of diarrhœa or constipation, but it also probably varies with the condition of the child, for it has been shown by test meals that in some cases of atrophy the stomach empties very rapidly. Variot[24] quotes Chahnet's observations that in children under 1 month carmine given with the food appears in the stools in less than two and a half hours, and is present in the stool up to eight hours after ingestion; and that in a child of 2 years, fed on sterilised milk, the periods are four and nine hours respectively. That these figures cannot be relied upon for metabolism purposes is proved by observing the time taken for barium to traverse the intestinal tract. In a series of cases of atrophic infants in which this has been done (Dr. C. G. Teall), the time required for the elimination of all the barium from the intestinal tract has varied from eight hours to three days. To make quite certain that the stool examined is one from a known fat intake, the fat in the food is estimated for three days before estimation of fat content of stool is undertaken. The method which I have adopted, and this method is used in all metabolism experiments, whether fat, protein, calcium, &c., is as follows:—

The experiment lasts over a period of eight days, during which period the feed is unchanged. For the first five or six days the fat intake is estimated every 24 hours. To do this, half an ounce of every feed is set aside during each period of 24 hours, and the actual amount taken at a feed is noted. At the end of the third 24 hours, the child is put on a metabolism bed for five days, during this time the whole of the stools (and in many cases the urine also) is collected, and each 24 hours collection of stool is dried and the fat estimated. The mean of all the 24 hours estimations of fat content of the feeds is taken as the fat intake; and the mean of the stool estimations as the fat output.

This method, I think, fulfils the essentials I have laid down. The chemical investigations have all been carried out for me in the biochemical department of the Children's Hospital by Miss E. M. Hickmans, M.Sc. Birm., to whom I am very greatly indebted.

There are probably many criticisms that can be made of our results, but two obvious ones can be met. The first is that drying the stools may alter the total fat, or the distribution of the fat in the stools. Holt, Courtney, and Fales, however, showed in their work, that, although the soap content of the acid stools of breast-fed infants is increased by drying, nevertheless in the stools of children fed on cow's milk, neither the total fat nor the distribution of the fat was affected. They, however, say that this distinction may not hold good in the case of acid diarrhœal stools, but such stools were not included in my series of cases.

The second criticism is that fæcal fat cannot be regarded as unabsorbed food fat only. In a recent paper Hill and Bloor[21] conclude, as a result of experiments on cats, that fat is to be found in the fæces, whether it is present in the food or not, and that fat in the food increases fæcal fat, but only to a comparatively small extent. These results, they think, favour the idea of a fat excretion from the intestine. Such a possibility must be admitted, but if fat excretion occurs in infants, the amount of fat excreted can only be very small, and is, indeed, negligible, for Holt found in a breast-fed infant an absorption of 99·2 per cent. of fat, and in an infant fed on cow's milk an absorption of 97·4 per cent. In our own experiments we have found an almost identical figure—namely, 97·7 per cent.—in an atrophic child fed on a mixture of cow's milk and skimmed cow's milk. In our experiments 398 stools were examined from 63 children, who were under treatment for infantile atrophy or pyloric stenosis. In some instances the same child was examined for more than one period, the actual number of children investigated being 51. In some of the cases every stool was examined, but in the majority 24 hours' specimens, as previously described.

Hutchison states that the fat output in the fæces varies directly with the fæcal weight, and forms approximately one-third of this. By fæcal weight he means the weight of the dried fæces. Holt, *et alia*, were not able to confirm this, their average figure was 34·5 per cent., but in children not exceeding six months old it was 37·5 per cent. of dried fæces, and the percentage varied from 11·2 to 82·6. Our results confirm their findings, and the average works out remarkably close to this figure, being 37·26 per cent., the actual percentages varying from 11·5 to 63·5. An average figure, however, where there are such extreme variations is of little value. As a general rule, the percentage of fat in the fæces varies directly with the percentage of fat in the food. Fat splitting throughout the series is good, and in two cases only did the neutral fat form more than 20 per cent. of the total fat. In Holt's series cleavage was always good, except in cases of diarrhœa, in which a large amount of unsplit fat was passed, in some cases forming 60 per cent. of the total fat in stools. This large increase in unsplit fat is presumably due to the rapid passage of food through the intestine. Several authors (Reeve-Ramsay,[22] Rosenstern,[23] Gray and Reynolds,[18] &c.) have suggested that in atrophy and pyloric stenosis there is weakening or diminution of the digestive ferments, and particularly of lipase. The results of the present series of experiments, and of former observations in pyloric stenosis, show that neither in atrophy nor pyloric stenosis is there any evidence of deficiency of pancreatic lipase.

Fat Absorption.

The average absorption from 43 observations in atrophic children gives a figure of 86·4 per cent., the lowest figure being 55·8 per cent. and the highest 97·7 per cent. If cases of pyloric stenosis after the Rammstedt operation are included, the average figure is unaltered. The table shows how this figure compares with other recent observations.

Hutchison: 73·5 per cent.

Utheim: 77 per cent. in all cases; 78 per cent. for cases which were observed over four and five-day periods.

Holt: 78·4 per cent. for all cases up to six months, excluding diarrhœa and severe diarrhœa; 81·1 per cent. for all cases up to six months in which digestion was not quite normal, but who were not suffering from diarrhœa; 88·6 per cent. in all cases—i.e., including children over six months, but excluding diarrhœa.

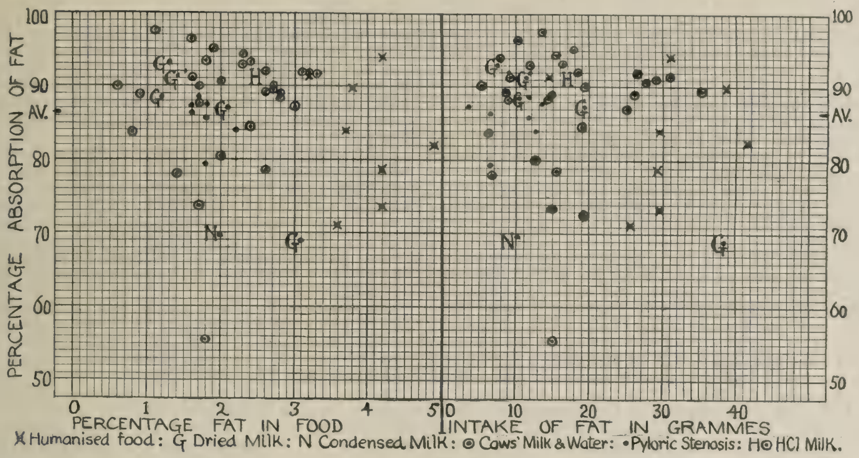
Distribution of Fat in Stools and Absorption of Fat on Different Dietaries.

Food.	Weight D.F.	% total fat.	Distribution % total fat.			Per 24 hours.			% absorption.
			Sap.	Free F.A.	Neutral fat.	Intake.	Output.	Absorbed.	
Dried humanised milk	10·2	47·4	67·2	23·4	9·4	30·0	5·1	24·9	73·9
Full cream dried milk	13·7	48·8	63·9	23·6	12·3	28·9	7·2	21·7	78·1
Half cream dried milk	2·6	26·4	82·3	9·1	0·9	9·9	0·7	9·2	91·0
Condensed milk	4·8	52·1	73·2	21·1	5·8	10·2	3·1	7·1	69·8
Milk, water, and lactose	—	41·2	73·2	14·9	14·4	—	—	—	—
Milk, water, and sucrose	5·8	37·6	71·3	22·6	6·1	20·6	2·2	18·9	89·2
Milk, water, and HCl	3·7	39·2	88·0	6·3	5·6	18·5	1·5	17·0	92·1
Milk, water, and D.M.	5·6	38·1	70·7	24·7	4·7	18·0	2·2	14·4	85·8
Skimmed milk .	4·9	15·4	81·5	10·0	8·5	8·6	0·7	7·9	90·4
(Pyloric stenosis)	3·8	32·7	77·8	15·7	5·8	11·2	1·3	8·5	86·5
Average (63 cases)	6·1	37·3	73·1	19·9	7·2	18·1	2·5	16·0	86·4

It is interesting to compare the percentage absorptions on different dietaries and with varying fat intake. Unfortunately the number of cases in some sections is a small one, but certain deductions seem justifiable. With the exception of one case fed on a condensed milk mixture, the lowest percentage absorptions are found with a dried humanised milk and a full cream dried milk. The highest percentage absorptions are found with hydrochloric acid milk (one case), a half-cream dried milk, and skimmed milk mixtures.

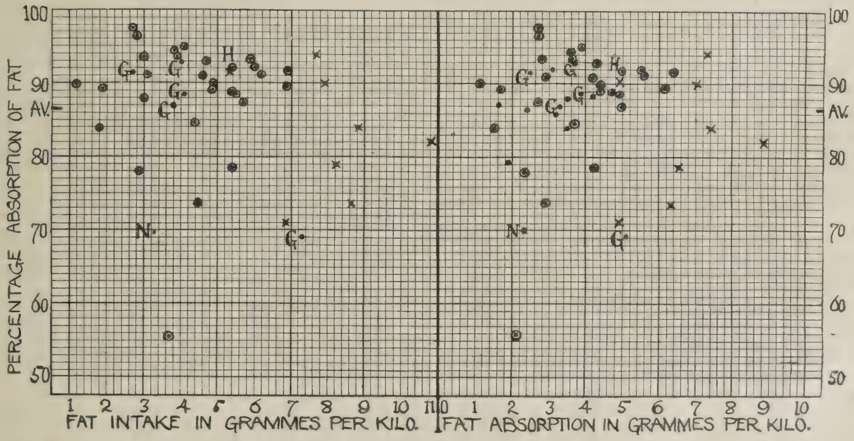
I am quite unable to account for the low percentage absorption and high total fat in dried fæces in the case of the child on condensed milk. The stool showed one of the highest figures for free fatty acid (36·8 per cent. of total fat) in the series. According to Holt the free fatty acid in diarrhœal stools is over 30 per cent. of total fat, yet this child did not have diarrhœa. The milk was sweetened condensed milk, containing 2 per cent. fat, but I know of no observations which, in the absence of diarrhœa, show a diminished fat absorption when the sugar intake is large. The stools were semi-formed and showed some fat curds. It is true that over the period of the experiment the child lost 3¾ oz., but in a subsequent experiment 4 oz. were lost; during this experiment the child was fed on a skim milk mixture (0·8 per cent. fat), and showed an absorption of 83·9 per cent. The stools were still semi-formed, but the free fatty acid averaged only 14·6 per cent. of total fat, and the percentage of fat in dried fæces was 13.

CHART 1. CHART 2.



I have not any figures for normal children, but Hutchison states that the average for his series was 89·7 per cent.; he does not, however, say whether they were artificially or breast fed, which is a point of considerable importance. For definitely normal children under six months fed on cow's milk modifications Holt's figures are 87·7 per cent. Comparing these figures with my own, it is quite obvious that fat absorption (in the absence of diarrhœa) is normal in infantile atrophy and pyloric stenosis.

CHART 3. CHART 4.



In the series of graphs the figures for percentage absorption have been compared with—(*a*) the percentage of fat in the food (Chart 1); (*b*) the amount in grammes of the fat intake (Chart 2); (*c*) the amount in grammes of fat intake per kilo of body-weight (Chart 3); and (*d*) the amount in grammes of the fat absorption per kilo of body-weight. (Chart 4.) From the graphs it is seen (1) that atrophic children show very good absorption figures for cow's milk modifications up to 3·3 per cent. of fat, a fat intake of 36 g. in 24 hours, or 7 g. per kilo of body-weight in the 24 hours; (2) that absorption figures for modifications of *dried* cow's milk are also good where the percentage of fat is 2·1 or less, the intake 20 g. or less, or 4·8 g. fat or less per kilo of body-weight in 24 hours; (3) that if modifications of dried cow's milk show higher fat values than this the absorption figures are nothing like so good (although in one case with a high fat percentage and intake the absorption figure was a very good one), and the weight of the dried fæces is higher.

Despite the fact that the digestion is normal (as shown by the figures for neutral fat), it appears, therefore, that there is much greater difficulty in absorption of fat when high fat content dried milk mixtures are used than when modifications of cow's milk are used. It is noteworthy that even with this difficulty in absorption the amount of fat in grams absorbed per kilo of body-weight may reach a very high value.

From these results I have come to the conclusion that high fat content dried milks are not economical foods from a fat standpoint, and although most of the children investigated put on weight when fed by this method (many doing very well), it seems reasonable to assume that the giving of an uneconomical food places a strain on the child's resources, which may well lead to what Finkelstein has called an "intolerance for fat." With the exception of one case, this is the nearest approach to Milchnährschaden, or intolerance for fat, that I have seen in my series of cases. The clinical experience of many observers, that half-cream dried milks produce better results than whole-cream dried milks, agrees with the above findings. The difficulty in fat absorption may possibly be associated with some alteration in fat emulsification, which occurs in the manufacture of dried milks, although it must be pointed out that of the two brands quoted, one is prepared by the spray system, by which it is stated that the emulsification is unaltered, and the other by the roller system. The criticism may be made that the dried humanised milk, to which I have referred, should not show a very high fat content; we have, however, found that this milk, used in the dilutions recommended by the manufacturers, always shows a high fat content.

The exceptional case to which I have just referred was apparently typical of Bilanzstörung (Finkelstein), or Milchnährschaden (Czerny). This child was an atrophic one, and lost 4½ oz. during the time of the experiment. He passed large white stools, which on drying gave a very high percentage of total fat and contained a large proportion of fatty acid; fat splitting was normal, but the fat absorption was the lowest in the series, being 55·8 per cent. The stools became somewhat less bulky when skimmed milk was given, but the loss in weight continued, and improvement did not occur until an ordinary milk mixture, containing ½ gr. of citric acid to the ounce, was given. On this the child gained weight, and the stools, although remaining pale, became normal in size. I would once more emphasise the rarity of this condition; it is the only one in our series, and was one of the last cases examined.

The findings of Holt and Fales[24] on fat requirements of children are interesting for comparison with our results. They state that healthy nursing children require 20 g. of fat daily, increasing to 40 g. at 6–7 months, or 4 g. per kilo of body-weight daily, but that infants fed on cow's milk should have smaller amounts than these; no actual figures, however, are given. The ideal fat intake according to Galbraith[25] is 18 g. daily in the first, rising to 28 g. in the seventh month. These values are calculated on the assumption that the breast milk contains 3·25 per cent. of fat. Our results show that many atrophic children fed on cow's milk can split larger amounts of fat, and also show that larger amounts than those stated, even by Holt and Fales, can actually be absorbed.

The presence of fat and soap curds in the stool is not certain evidence of fat indigestion; for in all cases where they have been observed, without diarrhœa, fat splitting has been normal and absorption satisfactory. The same remarks apply to the soap stool, which stool is in my experience not an abnormal one. Indeed, I am quite satisfied with the condition and prognosis in cases showing such stools, and I have not found the associated symptoms of Bilanzstörung in these cases. When, however, the soap stool is a very bulky one, as in some cases fed on high fat content dried milks, and in those very rare cases similar to the one I have just described, there may be, as already stated, diminished fat absorption.

From what has been said, it appears that fat indigestion occurs in infantile atrophy under two conditions: (1) When diarrhœa develops. In these cases as a result of peristaltic hurry, rapid passage through the intestine occurs, and fat splitting may be poor. (2) When high fat content dried milks are given. In these cases fat splitting is always good, the stool is a large one, and contains much soap and free fatty acid.

The treatment of artificially fed children in the first of these groups consists in putting them on a low fat dietary, and giving them carbohydrate in the form of one of the less fermentable sugars—e.g., dextrimaltose. The low fat dietary can be obtained by giving them skim milk, or a mixture of skim and whole milk; at times a condensed sweetened milk, diluted so as to give a low fat content, is found very useful, or one of the artificial foods used in the same manner. Protein milk has also proved valuable on occasions. When the diarrhœa improves, the fat content should be increased again, until the child is on a normal milk mixture.

A short preliminary period of starvation is often useful in these cases, particularly if the onset of diarrhœa is sudden (or possibly infective), but many children are so enfeebled that they are unable to stand this treatment. The treatment of the second group consists in giving a lower fat content dried milk, or substituting an ordinary cow's milk mixture for the dried milk.

ESSEX PUBLIC MEDICAL SERVICE.—The Essex Public Medical Service, which was recently formed to provide medical attendance and medicine for persons unable to pay the ordinary medical charges, has made a successful start in the county. Certain medical men have shown enthusiasm in its promotion, while local committees have been formed in many areas of the county.

THE PANCREAS AND DIABETIC METABOLISM.

BY HORST OERTEL, M.D. YALE.

(From the Pathological Institute of McGill University and the Royal Victoria Hospital, Montreal.)

I AM prompted to the following communication by the renewed interest in the nature and metabolism of diabetes mellitus which has received a strong stimulus by the discovery of "insulin," and further, by recently published observations of Geelmuyden on the formation of carbohydrate in the animal organism and on intermediary metabolism in diabetes mellitus. Geelmuyden's findings and conclusions fit so remarkably with those of Milne and Peters made in my laboratories in New York some years ago (1912),[1] that I think it worth while to draw renewed attention to them, especially as they did not attract at that time the consideration which, I think, they deserved.

Objections to Prevalent Beliefs Concerning Insulin.

The prevalent belief to-day seems to be that insulin is a secretion of the islands of Langerhans—hence the name "insulin"—and that it furnishes something which "aids in the burning of the blood-sugar." Both of these ideas, it seems to me, stand on a very insecure and, as I believe, erroneous basis.

The first contention—that the islands of Langerhans are a secretory unit for the purpose of an internal secretion—is supported by the following considerations: (*a*) Acceptance of morphological independence of the islands; (*b*) certain changes in the pancreas resulting from the tying of its duct; (*c*) specific staining properties of island cells; (*d*) evidence that in Elasmobranch and Teleostean fishes islands occur in independent locations removed from the main portion of the pancreas, and that insulin has been recovered from them; (*e*) certain older pathological evidence which placed essential diabetic lesions into the islands.

Against all of these considerations much may be said, but I shall be content to point out here what seem to me some of the most important objections.

The islands are not wholly independent structures which are simply carried by, and embedded in, the pancreas. Thus, the pancreas differs decidedly from the suprarenal glands in which two genetically different units have fused. The islands are embryologically derived from the same cell elements as the rest of the parenchyma, and they are particularly abundant in the embryonic and evolving pancreas. They can, by serial sections, be shown to have intimate connexion with the pancreatic parenchyma and even with the ducts, and indeed the resemblance to ducts and their intimate connexion with old ducts in certain pathological cases is most striking. Moreover, they cannot during certain phases of normal regression, but particularly in the abnormal, atrophic pancreas, strictly be separated from pancreatic parenchyma. Thus, also, in older subjects groups of acini may again take on the appearance of islands and typical acinar cells, and transition to acinar arrangement are sometimes seen in islands. Again, island cells or even groups of cells occur connected to other cells in pancreatic acini. Further, in pancreatic reductions from whatever causes (senility, emaciation, essential atrophy) there appear quite definite transition pictures. In advanced cases of this sort islands have thus largely disappeared without leaving any morphological evidence of destructive loss, such as a scar, or of degenerative changes in island cells. On the contrary, in general pancreatic atrophy island cells are often noted to become more numerous, larger, their connexions with parenchyma more intimate, without definite lines of demarcation, and in tinctorial qualities and arrangement they approach acinar or duct cells. This perplexing loss of islands by "evaporation," without leaving other morphological evidences of the mechanism of their disappearance than transitions to parenchyma, becomes thus intelligible. It is in these cases often impossible to demonstrate exactly where acinar tissue ends and islands commence, and numerous islands or duct cells appear in acini, while acinar cells are to be seen in islands. The conclusion, therefore, is strongly suggested, particularly by pathological material which has the advantage of throwing certain pancreatic changes and cell relations into greater relief, that the islands are an integral part of the pancreas, interchangeable with the parenchyma. The islands appear therefore as a phase in the constant morphological fluidity of the pancreas and consequently are an important feature of normal and pathological life of the organ.

These conclusions were reached by Milne and Peters, in conformity with findings of other authors, years ago, and continued investigations of a large number of normal organs representing different ages and evolutionary changes, combined with evidence from diabetic cases, have only strengthened my convictions in this respect. (In parenthesis it may be stated that I consider the diseased human pancreas, by exaggerating certain of these changes and morphological pictures, a more valuable source of information than the normal pancreas of lower animals.)

Experimental Cirrhotic Atrophy.

But now the experimental cirrhotic atrophy of the pancreas after ligature of its duct throws additional doubt on the independence of the islands, instead of supporting it. It is true that after ligature of the duct there occurs an extensive cirrhotic loss of pancreatic substance, and ultimately only solid clumps of cells remain embedded in fibrous tissue. These isolated clumps of remaining cells have at times the appearance of islands, but it is possible in many instances to trace the formation of such apparent islands through various stages back to atrophying acinar cells. Thus, also, it is possible to see in the earlier stages of this experimental pancreatic atrophy in the dog parenchymatous nodules still plainly visible, but at the edge of these there appear small pale cells. These may resemble the normal islands of the dog, but may generally be traced to some connexion with acini. I have, and so have others, made very similar observations in human cirrhosis of the pancreas. In other words, certain identification of islands as old persistent structures in a new cirrhotic environment is not possible, as old remaining parenchymatous nodules may take on this appearance and thus simulate islands.[2]

Identification of Islands by Staining.

There remains the identification of islands by specially designed staining methods (Bensley, Lane, Kirkbride, Jackson, &c.). This method seems to work well in some normal lower animals when immediate fixation is possible. But it is not applicable to all animals with equal surety, as shown by Milne and Peters, and it is entirely unconvincing in the abnormal pancreas and quite impossible to apply to pathological human cases. And I have learned that it is, especially in pathological cases, safer to depend upon general morphological appearances than upon complicated staining reactions of granular contents. That applies to other tissues as well.[3] But even if we admit that island cells have specific staining qualities, nothing else is indicated thereby except what we already know—i.e., that morphologically they differ from ordinary acinar cells. It does not, in any way, establish their structural and functional independence or invalidate the observations on transitions.[4] Indeed, the latest observations of Jackson on the islands of Elasmobranch and Teleostean fishes demonstrate their direct genetic relation to pancreatic ducts, although Jackson claims for them independence from parenchyma. The findings on insulin yields from these islands in fishes which carry them independently from the main part of the parenchyma, it would seem, have lost much value since insulin has been so generally found in other glands and tissues of the body. Indeed, some observers lean now toward the view that the pancreas is a "store-house for insulin."

[2] The pancreas follows in this respect similar changes in other glandular organs, when put into new (cirrhotic) environment, and it is necessary to retain only a very small amount of parenchyma (a nodule not larger than a pea) to prevent diabetes.

[3] Thus, Waugh has lately demonstrated in these laboratories that the oxidase reaction of myeloplasts varies under pathological conditions, and that this depends not only upon the degree of differentiation, but upon other, as yet obscure, variations from the normal cell type.

Pathological Evidence of Island Change in Diabetes.

Finally, when we come to the older pathological evidence of island changes in diabetes, which were at one time highly regarded as indicating their independent functional position, it must, I think, be admitted that sufficient evidence has now accumulated to throw considerable doubt on such changes in relation to diabetes. In the first place, observations by Reitmann, and further by Milne and Peters, have shown hyaline changes very similar to those in diabetes in non-diabetics, especially older persons or cachectics. Milne and Peters observed such hyaline changes in pancreatic acini of normal animals, which then resembled hyaline islands very closely. Reitmann regards focal hyaline degenerations as secondary consequences to cachexias or supervening infections to which diabetics are eminently liable (for example, tuberculosis, with hyaline or amyloid degenerations). According to my own observations such hyaline islands or foci are frequently found in diabetics with subsequent tuberculosis. They commence, very much like amyloid, with a capillary hyaline swelling. Whether such "islands" are always the Langerhans cell complex, or simply detached parts of parenchyma, cannot always be stated with certainty.

The evidence here presented indicates that the independent anatomical and functional position of the islands is not established beyond doubt, but to the contrary, rests on an uncertain basis. For these reasons certain investigators—notably von Hansemann, Herxheimer, Reitmann, and myself—recognise the importance of the pancreas in its relation to metabolism, not in a particular secretion of the islands of Langerhans, but in activity of the whole organ. Reference has already been made to the instability or fluidity of the whole pancreas, of which the islands are an indication and a phase. In fact, the whole pancreas is, as investigations of Reitmann, Anderson, and myself have demonstrated, in constant regression and progression. The pancreas resembles in this respect other important organs notably of internal secretion.[5] Atrophy, degeneration, collapse of acinar cells, and of whole acini are normal performances in the pancreas, and they are, under normal conditions, almost immediately compensated for by regenerative events. Thus the normal pancreas presents constant, sometimes quite extensive and varied pictures in loss and reconstruction of secretory parenchyma and architectural arrangement. This, as I have pointed out elsewhere, is of great pathogenic importance. For, while normally these two groups of processes—the regressive and the progressive—proceed side by side in orderly physiological balance, they may become upset and, by exaggeration or inhibition of one or the other, lead to pathological states. In this manner develops, in my opinion, the essential atrophy of the pancreas which is more commonly to be found in severe diabetes of the young than the cirrhotic (inflammatory) atrophy.[6]

Glycolytic Power of Blood and Tissues in Normal and Diabetic Conditions.

Prompted by their morphological investigations, which threw doubt on the independent structural and functional standing of the islands, Milne and Peters were led to continue their researches into certain experimental observations on the glycolytic power of the blood and tissues in normal and diabetic conditions. They found that the tissues in pancreatic diabetes could utilise dextrose, while the blood serum of depancreatised dogs possessed a marked diastatic action on glycogen, converting it into sugar, which action was increased, sometimes markedly, above the normal. Taking into consideration further that the glycogen contents in tissues are generally reduced in diabetics, they concluded that the disease would seem to depend on an excessive production of glucose from glycogen. This increased production may be the result of a failure of secretion of an anti-diastatic enzyme, or, it seems more probable, due to the action of accumulated substances in the serum which normally should be destroyed or altered by the pancreas. These substances increase slightly the diastatic power of the serum, but their chief action is more likely in the direction of causing the tissue cells to convert their store of glycogen into glucose. As an analogous process it is not unlike what in certain conditions occurs in the fat metabolism of cells. In all forms of diabetes, then, either as the result of pancreatectomy, ether, sugar puncture of the brain, or phloridizin, there is a rapid diminution of glycogen in the tissues. This is associated with an increased formation of glucose, at times considerable, and resulting in hyperglycæmia and glycosuria. The ability to form glycogen, however, still remains, so that new glycogen may continually be produced. This increased conversion of glycogen into glucose may be considered as due to the direct action of certain substances, such as phloridizin, ether, or products retained in the serum by pancreatic insufficiency, which increase the diastatic power in the blood serum, or act on the tissue cells so that they rapidly convert their store of glycogen into sugar." Thus Milne and Peters expressed themselves in 1912, basing their remarks on morphological and experimental investigations.

From this standpoint the recent observations by Geelmuyden on carbohydrate formation in the animal body and on the intermediary metabolism of diabetes appear of particular interest.[7] For Geelmuyden, quite in ignorance of the previous work of Milne and Peters, and by very different methods, has arrived at the conclusion that in diabetes occurs a hyperproduction of sugar from fats and proteids, and this he attributes to the uncontrolled action of adrenalin.[8] He interprets the beneficial effects of insulin as due to an inhibition, or at least to a decrease, in the sugar conversion. Thus, also, he explains the rise of the respiratory quotient after the administration of insulin, not by an increased burning of sugar, but as due to a retardation or cessation in the formation of carbohydrate from proteins and fats. In other words, he also believes that the pancreas "regulates" the action of adrenalin, that is, the conversion of glycogen and fat into sugar. If this step is omitted in the intermediary metabolism, hyperglycæmia and glycosuria result.

I am well aware that certain recent experimental investigations into the action of insulin such as by Bissinger, Lesser, and Zipf in frogs, and Noble and McLeod in the turtle, and some others argue rather against the views expressed by Geelmuyden as regards the antagonistic rôle of adrenalin and insulin in intermediary metabolism. But here it must be remembered that these observations were done with isolated organs (livers) of cold-blooded animals and are in contradiction to other observations, especially those of McLeod and Banting and their co-workers, who found a decided increase of glycogen and a corresponding decrease in fat in diabetes.[9] On the other hand, it appears from observations of Büchner and Grafe, and of Staub, that the action of insulin is so complicated and general that we are as yet far from fathoming its real relations to intermediary sugar metabolism. However that may be, all these investigations only indicate further the uncertainty and lack of fundamental knowledge in the action of insulin and nothing in these observations supports the view that "insulin" is an internal secretion of the islands of Langerhans. On the contrary, Büchner and Grafe's investigation point towards insulin action as a general cell function.

---

[4] I take these so-called "independent islands" to be only phases in the gradual phylogenetic condensation of the, at first, diffuse pancreatic substance to a localised organ.

[8] I consider it possible that other organs of internal secretion, like the thyroid, may also be here concerned.

I think sufficient evidence has been produced to show that there is at present still a reasonable uncertainty in the exact mechanism of the relationship of the pancreas to sugar metabolism. In my opinion, there exists enough morphological as well as experimental evidence, of which I have personal knowledge and in which I have faith, to question the independence of the islands and the conception of them as organs of internal secretion which are essential for the combustion of sugar.

NOTES ON A SMALL OUTBREAK OF TYPHUS FEVER IN ENGLAND.

By D. MORLEY MATHIESON, M.D. EDIN., D.P.H.,
MEDICAL OFFICER OF HEALTH, BIRKENHEAD;
AND
H. MASON LEETE, M.D. DURH., D.P.H.,
ASSISTANT MEDICAL OFFICER OF HEALTH, BIRKENHEAD.

IT is well known that there constantly exists a risk of the importation of typhus fever into this country by way of the great ports. This risk was especially marked during the years immediately following the end of the war, when the disease was epidemic in Poland and Russia, and when there was constant movement of refugees from infected areas. It was the fortune of Birkenhead to experience such a visitation in March, 1922. The disease was presumably introduced from abroad; we were, however, unable to trace the actual mode of entry—one of the chief difficulties in this connexion being that the first cases were not recognised and did not come under our notice until some five weeks after the onset of symptoms, and then only because further cases were occurring.

On March 29th nine patients were admitted to the Birkenhead Infectious Diseases Hospital, suspected to be suffering from typhus. Seven of the patients were removed from the Birkenhead Poor-law Infirmary at Tranmere, where they had been under treatment for varying periods. Two of these were convalescents, having been in hospital 30 and 20 days respectively; the remainder were recent cases—one had been in hospital four days, two two days, and two one day. Of the other two patients, one had been presented for admission at the Poor-law infirmary on March 29th, after the other cases had been removed, and was sent on to the infectious diseases hospital. The other was taken direct from her home. The two convalescent cases, admitted to the Poor-law infirmary at a time when an influenza wave was at its height, had been dealt with as cases of that disease, several of their symptoms being suggestive. It had been recognised, however, that certain unusual features were present; and with the appearance from the same or neighbouring houses of fresh cases which showed a similar clinical picture the suspicion was aroused that some other infectious disease of a specific character was being handled, and the medical officer of health was communicated with. The cases were seen in consultation with Dr. G. J. French, the medical superintendent of the Poor-law infirmary, on the evening of Tuesday, March 28th, and were removed to the infectious diseases hospital on the following day. A short observation of the patients in the infectious diseases hospital, particularly of the two most recent cases, confirmed the suspicion that they were suffering from typhus fever; and further corroboration followed when a positive reaction to the Weil-Felix test was obtained.

The history of two other patients who had been admitted to the Poor-law infirmary on Feb. 28th and March 2nd, and who had died there on March 6th and 7th respectively, leaves little doubt that they succumbed to the same disease. Finally, a boy of 4 years of age, a son of one of the above cases, who was admitted to the reception ward at the infectious diseases hospital for quarantine on March 31st, developed symptoms of typhus on April 7th, having been infected prior to admission. The total number of recognised cases was, therefore, 12. It would be unreasonable, however, to expect that this represents in its totality the extent of the outbreak, and that no cases escaped identification.

Particulars of the 12 cases are shown in Table I.:—

TABLE I.—*Typhus Cases: Age, Sex, &c.*

Case No.	Init.	Age.	Sex.	Probable date of onset.	Admission to—		Result.
					P.L. hosp.	I.D. hosp.	
1	M.L.	32	F.	20/2	27/2	29/3	Recovered.
2	T.O.	18	M.	23/2	28/2	—	Died 6/3/22.
3	H.O.	53	F.	23/2	2/3	—	Died 7/3/22.
4	I.O.	24	F.	2/3	9/3	29/3	Recovered.
5	J.O.	52	M.	20/3	27/3	29/3	,,
6	L.O.	20	F.	23/3	27/3	29/3	,,
7	J.O.	28	M.	23/3	28/3	29/3	,,
8	W.O.	24	M.	27/3	28/3	29/3	Died 12/4/22.
9	M.R.	31	F.	23/3	—	29/3	Recovered.
10	M.R.	44	F.	19/3	25/3	29/3	,,
11	C.D.	44	F.	23/3	—	29/3	,,
12*	J.R.	4	M.	7/4	—	7/4	,,

* Developed disease while in reception ward, to which he was admitted on March 31st.

Clinical Features.—The clinical features of the ten patients treated at the infectious diseases hospital differed considerably. It might, in fact, be said that among this comparatively small number all types of cases were seen, from the mild case which, had it not been for the history and the diagnostic tests applied, would certainly have escaped detection, to the severe form resulting in a fatal issue. One outstanding feature given in the history of all the patients was *headache*, generally coming on suddenly and in a severe form. Other symptoms were not so constant. The cases may be classed as follows:—

Convalescent (no symptoms of disease on admission to infectious diseases hospital) (Cases 1 and 4) ..	2
Mild (Cases 9 and 12)	2
Moderate severity (Cases 5 and 6)	2
Severe (Cases 7, 8, 10, and 11)	4

The individual cases, however, showed such differences that it will be best to describe each separately.

CASE 1.—Female aged 32. Took ill Feb. 20th, 1922. Headache, sore-throat; went to bed at once. Admitted to Poor-law infirmary (P.L.I.) on the 27th, but does not remember this. On admission to infectious diseases hospital (I.D.H.) she was not complaining; appeared in ordinary health, gave a faint positive diazo-reaction [1] and presented no other features of clinical interest. Discharged recovered on April 13th.

CASE 4.—Female aged 24. Took ill Feb. 23rd, suddenly, in a shop, went "light-headed," kept on feet for a week, went to bed on March 2nd, feeling "ill all over" and having pains in the chest. On admission to I.D.H. was not complaining, and beyond a faint positive diazo-reaction, which persisted for four days after admission, there were no features of clinical interest. Discharged recovered on April 13th.

---

[9] The diverse and conflicting observations in this regard suggest that different animal species may have a different carbohydrate metabolism.

[1] A doubtful reaction. In Table II. only quite definite positive findings have been entered as "positive" and doubtful ones regarded as "negative."

CASE 5.—Male aged 52. Took ill March 18th, complaining then of pains in head and back, shivering, cough. Pains spread all over and "couldn't get out of bed." Was treated at home for a week and admitted to P.L.I. on the 27th. On admission to I.D.H. on the 29th looked ill, was complaining of headache and cough, and had some expectoration. T. 102·2°, P. 96. Evidence of arterio-sclerosis; slight bronchitic signs throughout the chest, slightly deaf, dazed and rather resentful of questions. One or two indefinite spots on the back but no real rash. Diazo-reaction positive. Remained in much the same state, chest symptoms being prominent, till April 2nd, when there was a sudden improvement, the patient seeming better in every way. The next day he not only demanded food vigorously, but was most anxious to get up. After this crisis he rapidly improved and convalescence was uneventful. Discharged recovered on the 27th.

CASE 6.—Female aged 20. Took ill on March 23rd, when she complained of headache, swollen glands in neck, and a pain in the right shoulder. Took to bed on the 25th feeling much weaker and worse in every way. Admitted P.L.I. on the 27th and I.D.H. on the 29th. On admission mentally quite clear, complaining of headache, sore neck, weakness, and cough. On examination no rash was seen. Diazo-reaction brilliantly positive; patient looked ill, under-nourished, and anæmic. T. 102·4°, P. 100. Headache and cough persisted for a few days, but by April 4th patient definitely improving, practically convalescent by the 6th. On the 7th complained of pain in left calf, which was tender on palpation, and the whole leg markedly swollen—a diagnosis of popliteal thrombosis was made. This complication cleared up after about a week, when the patient made a good recovery. Discharged recovered on May 9th.

CASE 7.—Male aged 28. Took ill on March 21st with shivering, cough, and headache. On admission to I.D.H. on the 29th complained of "being sore all over," but could not give a connected account of how he felt, as he was distinctly delirious—a low muttering stupor. Obviously ill; a cough, markedly dilated pupils, tongue furred; a definite general rash, profuse on trunk, more marked on back than on chest and abdomen, well marked on legs and arms, forearms showing fewest spots. Face blotchy but showed no spots. Individual spots at this stage resembled those of enteric. Two days later the rash was even more marked, fresh enteric-like spots appeared, and in addition deeper subcuticular spots were showing up well, giving the skin a distinctly mottled appearance. During this time patient was very ill. Delirium continued, and the bowels were rather loose, tremor of lips and hands noted. On April 6th rash began to fade and there was a distinct improvement in general condition—the patient being clear mentally and complaining of hunger for the first time. Next day the improvement was maintained and the patient was practically convalescent. The change, in a day or two, from a profoundly ill to an almost well man was very striking. No special features of interest during convalescence. Patient was discharged recovered on the 27th.

CASE 8.—Male aged 24. History given by patient was that of waking up on March 25th with headache, cough, pains all over, and a shivering attack. He was up during the next two days, but felt ill all the time. On the 28th he took his brother (Case No. 7) up to the P.L.I. and, it being noticed that he was ill, he was detained there. On admission to I.D.H. he was complaining of intense headache, cough, and pains in back and hips. Although he was obviously ill, his mental condition was clear. Slight deafness. T. 104·2°, P. 96. Brilliant diazo. Well-marked rash on sides of neck and trunk (most profuse on back). Spots noted on arms, none on legs. Individual spots small, lenticular, slightly raised, pinkish papules not unlike enteric. None seen on face. Next day patient much the same, but rash markedly petechial on right forearm, being obviously brought out by application of tourniquet for vein-puncture on the previous day. On April 2nd rash still more marked, and subcuticular elements were made out, the distribution remaining as before. On the 3rd patient's condition worse; he still complained chiefly of headache and was markedly cyanosed. Restless and delirious at times. Next day much worse, semi-conscious, restless, more cyanosed; constant hiccough. Rash well marked. He continued much in this state for several days, mental condition very confused, with struggling, muttering, and shivering fits. On the 8th rash still very marked and fresh spots noted on arms; general condition as before. On the 10th, as his condition was getting desperate, it was decided to give him whole blood intramuscular injections from a typhus convalescent—adopting the technique used with success by Zingher in cases of toxic scarlet fever. The donor was his father (Case 5), then in the twenty-fourth day of disease and the tenth of his convalescence; 125 c.cm. of whole blood were transferred—the temperature fell to normal within 12 hours (? artificial crisis), but there was no real improvement in the other symptoms. On the 11th he was still very ill, but more drowsy and not so restless. He died on the 12th.

CASE 9.—Female aged 30. On March 22nd this patient complained of severe headache and went to bed—the only other symptom complained of was some stiffness in all joints. On admission to I.D.H. (on the 29th) she still had some headache but otherwise did not complain. Face flushed and tongue furred. She was 7½ months pregnant. Diazo positive. There was an indefinite rash present consisting of a few papules on the chest and rather more on the back—under normal conditions they would hardly have attracted attention. She slept well and showed no further symptoms during the next few days. By April 6th temperature was normal and patient convalescent. Discharged, recovered, on the 27th.

CASE 10.—Female aged 44. Patient too ill to give any definite history. She was in P.L.I. from Jan. 30th to March 4th, suffering from pneumonia. Returned home on the 4th and took ill again on the 19th, when she collapsed, had severe headache and malaise. Readmitted to P.L.I. on the 25th and on that date was stated to have had a rash. On admission to the I.D.H. on the 29th she was very ill and exhausted, too weak to speak and with rapid respirations. A few spots on the abdomen and chest and rather more on the back—none noted on limbs. T. 100°, P. 129. Diazo brilliantly positive. This patient lay in an absolutely exhausted state until April 6th, when she showed signs of more life and gradually began to pick up strength. Discharged, recovered, on the 27th.

CASE 11.—Female aged 44. This patient took ill on March 23rd when she suddenly began to vomit, had pains all over and a severe headache. On admission to I.D.H. on the 29th she only complained of a "thick feeling in the throat." Face flushed and somewhat bloated. Distinct deafness, pink conjunctivæ, and small pupils. Cough. Slightly cyanosed. T. 100·2°, P. 116. Diazo brilliantly positive. Well-marked rash on chest, abdomen, back, and upper arm; most profuse on back; none on legs. Elements were somewhat large and persisted after pressure—subcuticular mottling well seen—i.e., spots resembling faint indefinite petechiæ. Patient dull, stupid, and obviously ill. On March 31st rash definitely petechial on forearms, particularly so on right side, where tourniquet had been applied; also a few petechial spots on legs; stools loose and light yellow. For three days this patient was acutely ill—marked rash with the subcuticular element very obvious, dusky red face, red eyes, small pupils, tremors, stupid, deaf, muttering. On April 4th she showed a distinct improvement and smiled for the first time. The rash was beginning to fade. Steadily improved, but on the 11th (twentieth day of disease) she developed a left otorrhœa. This gave rise to no trouble, and was dry within a week, after which she made an uneventful recovery. Discharged, recovered, on the 27th.

CASE 12.—Male aged 4. A son of Case 9. Admitted to reception ward 8 on March 31st together with other typhus contacts. On April 7th had temperature of 100·8°, was fretful, and there was a definite rash on the trunk and limbs. Spots widely separated, resembled enteric spots, and very distinct. Constitutional symptoms slight. He was transferred to the typhus ward. The diazo-reaction was strongly positive. The next day the rash was more profuse, though the elements were not so distinct, this being due to the development of subcuticular mottling. Both trunk and limbs were involved—it was most marked on buttocks, more on back than front and more on legs than arms. Throat slightly congested and tongue slightly furred, mucous membranes of mouth were clear and shiny, face blotchy and showing a slight tremor. Slight cough; child still fretful though not really ill. Sleeping and eating well. No further symptoms. Rash began to fade on the 9th, and gone by the 12th. Uneventful convalescence. Discharged, recovered, on May 9th.

Diagnostic Features.

The difficulties in the way of the early diagnosis of a disease with which few practitioners in this country have had any practical acquaintance are, naturally, very great. At the same time, once it was recognised that it might be typhus we were dealing with, the diagnostic difficulties became very much less. Once typhus was in mind, the history of a sudden onset, the presence or history of a rash, positive diazo and Weil-Felix reactions, left no room for doubt that a case *was* typhus. Here it must be emphasised that clinical and laboratory findings must be taken together—it is a mistake to speak of clinical as opposed to laboratory diagnosis, and a diagnosis can only be arrived at by a careful summing-up of all factors.

With regard to the differential diagnosis, only two other diseases needed seriously to be thought of: influenza and enteric. (*a*) With regard to the former it is wise to adopt an attitude of caution; as a convenient term for describing an acute febrile condition without specific character it may be very useful, but apart from epidemics such as occurred in 1918–19 it may be seriously questioned whether the disease is a clinical entity. At all events, in every case of so-called influenza every other possibility must be reviewed. In the outbreak dealt with the presence of a rash, the characteristics of this rash, and the presence of a positive diazo-reaction sufficed to exclude influenza. (*b*) Enteric is more difficult, and the distinction is mainly clinical, the important points being sudden onset, type of rash, particularly as to its distribution, and the presence of subcuticular and hæmorrhagic elements, the absence of abdominal symptoms, and, though too late to be of much practical importance, the crisis, and the remarkably sudden improvement that occurs then. The Widal test is of no distinctive value as it is frequently positive in typhus. The Weil-Felix reaction is of great practical value, though being a non-specific reaction further experience of its presence or absence in enteric is to be desired.

In the present investigation the Weil-Felix tests were carried out in the Birkenhead municipal laboratory, living cultures of *B. proteus X 19*, kindly supplied by the Lister Institute, being used. With regard to the technique of the tests, we obtained much help from a paper published in THE LANCET on Feb. 4th, 1922, by Prof. James Wilson.

So much stress has been laid upon the laboratory helps to diagnosis that it will be well to give a summary of the findings in each case in Table II. It will be seen that the Weil-Felix test was positive in all cases. It was not present in one case on the sixth day, but appeared later, and another previously positive was negative on the fiftieth day. The diazo-reaction was positive, generally speaking, throughout the febrile period and became negative after the crisis. The Widal was irregular, being positive in three out of the nine cases investigated.

TABLE II.—*Results of Laboratory Findings: Weil-Felix, Diazo, and Widal Reactions.*

Case No.	Weil-Felix R.	Diazo R.	Widal R.
1	P. 1/400.... 39th. N. 50th.	N. 38th.	N. 50th.
4	P. 1/200 35th.	N. 37th.	
5	P. 1/400.... 13th, P. 1/6400 23rd.	P. 12th and 14th, N. 16th.	N. T.A.B. 23rd.
6	P. 1/400.... 12th, P. 1/400 21st.	P. 8th and 13th, N. 17th.	N. T.A.B. 21st.
7	P. 1/25,000 14th, P. 1/6400 21st.	P. to 17th, N. 21st.	P. T. 1/100 21st.
8	N. 6th, P. 1/800 12th and 1/1600 17th.	P. 6th to 19th (died).	P. T.A.B. all 1/200.... 17th.
9	P. 1/400.... 13th, P. 1/200 22nd.	P. 10th and 11th, N. 13th.	N. T.A.B. 22nd.
10	P. 1/400.... 13th, P. 1/200 25th.	P. 12th and 15th, N. 17th.	N. T.A.B. 25th.
11	P. 1/400.... 8th, P. 1/400 21st.	P. 8th to 15th, N. 17th.	P. T. 1/400.... 21st.
12	P. 1/800.... 6th.	P. 2nd to 10th, N. 11th.	N. T.A.B.... 6th.

P = positive. N. = negative.
The ordinal numbers represent days.

Note.—All days referred to are days of disease. The figures in the agglutination tests show the highest dilution in which the test was positive. A series of dots after the figure—e.g., 1/400....—indicate the limit of the test, and it is possible that a higher end-point would have been obtained had this been tested for.

Method of Spread.

It has always been recognised that typhus tends to flourish and spread in places where dirt abounds—rooms with dirty floors, dirty walls, dirty bedclothes, calling for the use of soap and water; and dirty air, calling for the use of open windows. It has also long been known that another disease is fostered by the same conditions—pediculosis. Recent investigations have shown that these two diseases are associated to this extent at least, that the infection of typhus is carried from person to person in one way and in one way only—by lice. After feeding on and absorbing blood from a typhus patient they transfer their attention to a healthy individual; and in due course the latter develops the characteristic symptoms of typhus. Nits from an infected louse can hatch out young lice which are infected and can carry the disease.

Administrative Action Taken to Check Spread of Outbreak.

The chief steps taken in dealing with the outbreak under consideration may be briefly indicated.

(*a*) Removal of all recognised cases to the infectious diseases hospital. All patients were passed through a delousing room before entering the ward. Here hair was shaved and measures taken to remove all lice and lice eggs (nits). Protection in the form of special overalls, &c., were devised for the nurses, medical staff, porters, &c.

(*b*) Removal of contacts from patients' homes to an emergency quarantine station fitted up in the infectious diseases hospital. All these individuals were also deloused and bathed before admission.

(*c*) Search for all persons who had been in contact with known cases of the disease, and constant watch for new cases.

(*d*) Disinfection by steam of all clothing, &c., used by patients and contacts. Destruction of rags and other rubbish—present in abundant quantities in many houses where space is limited.

(*e*) Disinfection and disinfestation of houses.

Most of the houses were of a very poor and dirty type. The disinfection and disinfestation had to be carried out at considerable risk to the men engaged. Walls, ceilings, floors, and furniture were washed with corrosive sublimate solution, and sulphur fumigation was carried out. Similar steps were also taken in connexion with the wards, &c., at the Poor-law infirmary which had been occupied by patients suffering from the disease. With the exception of the case which developed in quarantine (No. 12), and which presumably contracted the disease before admission, no further cases occurred.

Our acknowledgment and thanks are due to Dr. French for certain clinical data collected regarding patients during their stay in the Tranmere Poor-law Infirmary, and to Dr. Percival Letts, of the Ministry of Health, and Dr. C. O. Stallybrass, both of whom kindly discussed the cases and the outbreak generally.

HYSTERICAL BILATERAL PTOSIS AND CONVERGENCE EXCESS.

WITH NOTES OF A CASE.

BY SAMUEL LODGE, O.B.E., M.D. DURH.;

> "To the disturbances of the functions of the eyes we are often able to apply tests more delicate than those which pertain to the investigation of other organs, and therefore should be able more accurately to interpret their symptoms."—*G. E. de Schweinitz.*

IN investigating curable nervous affections which consist of involuntary dissociation of voluntary functions, it is well to bear in mind that symptoms depend mainly on the site of a lesion. Any motor disturbance may be localised approximately. In the lower limb, loss of every movement except flexion, adduction, and internal rotation of the thigh points to the cauda equina; astasia abasia, in which the patient is unable to stand or walk, though capable in the recumbent position of performing all movements correctly, may logically be referred to some level higher than the Rolandic cortex. In a case of hemi-anæsthesia, inability to feel the vibrations of a tuning-fork on the affected side of the sternum, although the vibrations must be conducted to the normal side, localises the interference to a level at which all forms of sensation from both sides of the body become associated together in kaleidoscopic patterns which are influenced by heredity, training, or the needs of the moment. Let him who doubts consider the simple sensations analysed in judging the direction of the wind by holding up a moistened finger to the breeze, and then ponder over the synthesis of Paganini's amazing execution on the single G-string which held vast audiences spellbound. For the exercise of every function neurones become associated, each centre being guarded by its synapses.

Complex Reflexes.

Where neurones exist reflexes occur, and there is merely an anatomical difference between the mechanism which enables a pithed frog to flick a piece of blotting-paper wet with vinegar from its back, and that which prompts a hedgehog thrown into a pond to curl up until satisfied that no immediate danger threatens before swimming for dry land. When the element of heredity comes into play constant responses to given stimuli merge into instincts (e.g., the migration of eels, on arriving at maturity, to the deepest part of the Atlantic to spawn). Other complex reflexes are of a purely acquired origin. Scott in his novel, "The Pirate," alludes to a seal which flapped its tail to the tune of "Caberfae" and acknowledged none other whatever. A wire-haired fox terrier was always on the alert when his master was about to leave his office; by experiment it was found that the dog, even though apparently fast asleep, recognised the faint click of the lock of a safe as an infallible sign that work was over, and jumped to his feet with every manifestation of eagerness to depart. Pavlov observed that if he regularly rang a bell before a dog's feeding times the sound alone eventually made the animal's mouth water, but under certain circumstances, if food were withheld, the animal fell asleep, showing that other reflexes were inhibited. He termed this a "conditioned reflex." In man, from the time an infant first learns to sleep at the sound of a lullaby, conditioned reflexes of all grades of complexity are being developed, exercised, and lost—one may regard them as psychological units.

An Illustrative Case.

In the case described hereunder the emotions induced by certain surroundings became the signal for the onset of a peculiar disturbance of the ocular muscles.

On March 24th, 1922, a widow, aged 45, complained that suddenly, whilst in church, she had become unable to open her eyes, and had to be led home. In 1902 we had removed the crystalline lenses for high myopia. The vision, at first R. 6/9 with −5·0 sph., L. 6/12 with −1·0 cyl. ax. 180°, by 1912 had gradually deteriorated to R. 6/36, L. 6/15; esophoria 7°. The patient had suffered from ethmoidal trouble complicated by asthma, but resection of the middle turbinals in 1921 had completely cured both conditions.

Condition on Examination.—The lids were found closed as in sleep; when the patient attempted to open them, the forehead became furrowed and the eyebrows arched, but the palpebral aperture did not open, nor was the head thrown back. On raising the lids with the fingers the eyeballs were revealed in a state of extreme convergence, so that images of reflected light fell external to the cornea, slightly above its horizonal diameter. Vision was reduced to hand movements; the pupils were normal and reacted to light.

Suggestion was brought to bear, and to reinforce it a few minims of alcohol were injected into the lids. They soon commenced to rise slowly, the lid last injected lagging behind its fellow; the entire syndrome disappeared and the vision regained its customary acuity. There was a slight relapse on the following Sunday.

On further inquiry it was found to be no mere coincidence that the attacks occurred on Sundays. A memorial service for the patient's soldier husband, killed in the war, had been held at Grimsby; she intended to revisit the town, and the prospect of attending divine service there brought back poignant memories. We urged her by no means to abandon this intention, assuring her that she might make her pilgrimage, if not without sentiment and emotion, at least without fear of loss of sight. She overcame her forebodings, and by acting on this advice gained freedom from further attacks and a new spirit of confidence in the future.

As a rule, the association between a recrudescent emotional tone and an automatic action is set in early life—here the history covered but five years; yet no other relevant psychical experiences were discovered, and the symptom seemed appropriate to the context.

We are not alone in supposing that centres concerned in emotional states may usurp control of the normal channels of communication between the brain and other organs. According to Prof. Hering, "In asthma afferent nerve impulses resulting from certain stimuli produce a reflex contraction of the bronchial muscles and a narrowing of the bronchioles. The reflex may become a 'conditioned' one, and be induced by any afferent impulse resulting from a stimulus which has been associated with its occurrence. The pathways in time are so 'grooved' that the reflex takes place very readily, and is excited by any afferent nerve impulse which has previously been associated with asthma."

The variety of manifestations, if we include the rarer visceral, trophic, and vaso-motor forms, is almost infinite, but Nature protects most jealously the functions on which life itself depends. Among the distinctive properties of the synapses of the higher centres is their relative susceptibility to anæsthetics. The fact that the functions least affected by hysteria are those last affected by anæsthetics, and vice versa, is utilised in the diagnosis of phantom tumour. Complications of hysteria are in a different category; in functional dysphagia, for instance, the unbalanced diet may produce enlargement of the spleen and secondary anæmia, and after restoration of normal deglutition failure of the thyroid to cope with the increased food-supply (Vinson). Medical literature records many instances of organic complications which may ensue when voluntary functions undergo involuntary dissociation from curable causes.

We have described an unusual disturbance of the ocular muscles, impossible for a malingerer to simulate, but possibly modified by the pre-existing state of refraction and muscle balance. Its recurrent onset in response to emotions produced by certain definite surroundings suggests a "conditioned" reflex, and lends support to the hypothesis that centres concerned in emotional states may usurp control of the normal channels of communication between the brain and other organs.

THE MEDICAL TREATMENT OF CATARACT.

BY INGLIS TAYLOR, M.B., C.M., F.R.C.S. EDIN.,
CONSULTING SURGEON, WESTERN OPHTHALMIC HOSPITAL,
MARYLEBONE-ROAD, N.W.

FOR years ophthalmic surgeons have been striving to find some means of curing, or at least delaying, the advance of cataract beyond the stage when work must be given up, and financial conditions make its continuance imperative. Until fairly recently I was very sceptical that such a desirable end would be attained, but now I know better. This excellent result is chiefly due to the exertions of Badal and Dor, though many others were working on the same lines.

Badal began with the assumption that cataract was due to a dehydration (sclerosis) of the lens, and used iodine in alkaline solution as a collyrium, and later for ocular baths, with some success. Dor,[1] in 1919, demonstrated that cataract is the result of hydration of the lens, the hydration being due to the fact that the blood contains hydrating ferments, such as occur in the blood-serum of rabbits when naphtholin is ingested, and in the serum of certain diabetics ; in both conditions the frequency of cataract is well known.

---

[1] Clinique Ophtalmologique, June, 1919.

Calcic-Alkaline Iodide Treatment.

Dor's treatment, therefore, consists principally in adding the dehydrating action of calcium to the lignifying and other actions of iodine. This preparation was still used as an eye-bath until Chauvin, director of Blache Laboratories, brought it out in the form of an ointment, under the name of calcic-alkaline iodide, and in this form it is now used. As a bath it frequently caused irritation, and the treatment twice a day, continued if possible for half an hour each time, was very irksome.

The ointment is in most cases quite painless, and should be so, but like badly mixed hydrarg. oxidi flav. it can be very painful ; when pain occurs the tube should be changed for another. Messrs. Rouse and Co., chemists, of Wigmore-street, London, W., obtained a supply of the tubes for me about a year ago, and having given it a fair trial, I am able to express a very strong opinion in its favour.

Naturally, the more incipient the cataract when brought under treatment the more easily is it absorbed, but it must not be thought that only these very early cases are successfully treated. Though strongly commending the treatment, I have had too much experience in operating to have any doubt that absorption is not the treatment for an advanced case, nor is it claimed that the treatment should be used in such cases. All told, I have had about 20 cases under treatment, but all of these cannot be counted as a fair indication of the merits of the treatment, as at first I was inclined to try the effect on cases which were too advanced. Another cause of reduction in numbers, was, I am sorry to say, the want of faith in trying a new remedy, of the medical profession, ophthalmic and otherwise. Patients applied to their general practitioners or through a friend to the friend's oculist, and were informed there was no cure for cataract except operation. They naturally ceased to attend, and now have the weariness of waiting. Of the rest I treated, I now have four or five with full vision, and the others are in various stages of improvement.

The following is a typically good case :—

Mrs. G., aged 59 ; Sept. 11th, 1923, no cataract visible in right eye, pupil not dilated, V. = 6/6 ; in left eye cortical cataract, and two of the striæ meeting in the middle, V. = 6/24. Ung. calcic-alkaline iodide ordered for left eye only.

On Oct. 15th, R.V. = 6/6 part c. diff., L.V. = 6/12, all but one letter. Ung. ordered for both eyes.

On Nov. 19th, R.V. = 6/6 a little slowly, L.V. = 6/9, all but one letter.

On Jan. 22nd, 1924, V. = 6/6 all but one letter, each eye quickly, and the last letter after hesitation.

To illustrate improvement, I give other cases.

Miss S., aged 51. July 17th, 1923, cortical cataracts, V. = 6/60 dimly, not improved with glasses. On Sept. 6th, V. = 6/36 dimly and with −2 D. sph. 6/36 clearly. On Jan. 10th, 1924, V. c. −2 D. sph. = 6/12 (2) each eye.

Mrs. K., aged 58. On Sept. 12th, 1923, cortical cataracts. R.V. c. +1·5 D. cyl. 6/12, L.V. c. +0·5 D. cyl. 6/9. On Nov. 27th, c. above R.V. 6/6 (3), L.V. 6/6 all.

Miss B., aged 64. On Sept. 17th, 1923, early cortical cataracts, c. + 1 D. sph. and cyls. V. = 6/6 slowly. On Jan. 31st, 1924, c. above V. = 6/5 (3) each eye.

Mrs. A., aged 48. On Oct. 29th, 1923, cortical cataracts. R.V. c. +1 D. cyl. = 6/9, L.V. c. +0·5 D. cyl. = 6/6 a few. On Dec. 7th, 1923, c. above R.V. = 6/6 a few, L.V. = 6/6 all.

Mrs. J., aged 73. On Nov. 15th, 1923, irregular cataracts. R.V. < 6/60, L.V. c. +0·5 D. sph. = 6/12. On Jan. 11th, 1924, R.V. < 6/60, L.V. c. above several letters of 6/6.

In another case, an old lady, aged 82, with advanced cataract in left eye, early nuclear in the right eye. V. = 6/6 part and after treatment = 6/5, so age is no impediment to treatment.

It is claimed that the treatment overcomes the opacity of the lens, sometimes for a considerable period, but at present it seems to me that to retain normal vision a fortnight without treatment is long enough at a time.

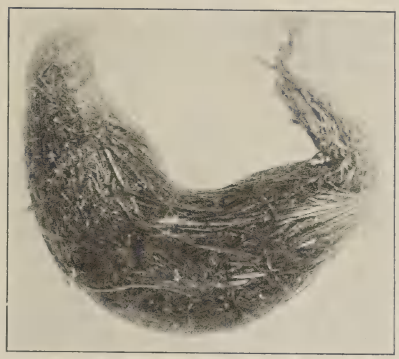
Clinical and Laboratory Notes.

A CASE OF "HAIR-BALL" IN THE STOMACH OF A TEN-YEAR-OLD GIRL.

By GERTRUDE M. A. HERZFELD, M.B., F.R.C.S. EDIN.,
ASSISTANT SURGEON, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH ; SURGEON, EDINBURGH HOSPITAL FOR WOMEN AND CHILDREN.

THE following case is, I think, worthy of record :—

A girl, aged 10, was sent into the Royal Hospital for Sick Children by her doctor in Aberfeldy, who stated that following an attack of jaundice in spring, she had become emaciated, complained of pain at the umbilicus and of inability to take food. The history given by the mother before operation was brief and to the above effect ; the child was evidently going rapidly downhill. No family history of tuberculosis. No serious illnesses.



"Hair-ball" of grass, reeds, string, cotton, and hair, removed from the stomach in the case described.

Condition on Examination.—Patient was a well-grown but rather emaciated girl ; she was very shy and reserved and answered questions with reluctance. Asked to show the site of any pain she always pointed exactly to the umbilicus. The abdomen moved freely and showed no distension. On palpation the upper parts of both rectus muscles appeared to be somewhat resistant, but there was no true rigidity and no pain was elicited on pressure. There was no tenderness over the cæcum or kidneys and no enlarged mesenteric glands could be made out. The urine on centrifuging showed an occasional pus cell and red blood cell, but not sufficient in any way to account for the patient's condition. No definite diagnosis was made ; the possibilities of appendix dyspepsia and T.B. mesenteric adenitis and Meckel's diverticulum were considered. Laparotomy was advised as the child was evidently ill and going downhill.

Operation.—Laparotomy was performed on Sept. 13th. 1923. A right rectus incision 3 inches in length with the centre just below the umbilicus was made. The cæcum and appendix were sought for first and found to be healthy. There were no enlarged mesenteric glands and no Meckel's diverticulum could be found. On passing the hand into the upper abdomen a hard mass, lying transversely across the middle line, was felt above the umbilicus ; it felt very like a leather-bottle stomach. The incision was enlarged for two inches upwards and the greatly distended stomach presented, containing a hard tumour, in shape and size somewhat like a double banana, which completely filled the stomach and passed into the first part of the duodenum, also greatly distended.

A horizontal incision was made in the anterior wall of the stomach and the tumour as depicted in the photograph was removed. It was seen to consist of grass, reeds, string, cotton, and hair, inextricably mixed into a solid mass. A piece of string passed from the tumour into the duodenum and had to be cut. The opening in the stomach was closed by two layers of catgut and the abdominal wall was sutured.

The child was not upset by the operation, and apart from being highly excitable and almost hysterical for the first two days, she made an uninterrupted recovery and was discharged on the twenty-first day much improved in general health.

Details of History.—Following the operation the mother was interviewed again, and a much more detailed and more enlightening history was obtained, the salient points of which were: From the age of 3 the child had been very nervous and easily frightened. She went to school at the age of 6, but disliked and feared the teaching. She became more nervous, and even the passing of a horse and cart on the road to school terrified her. She was very sensitive and very affectionate and always wanted to be by her mother's side. A year before admission her mother noticed that she was always chewing whatever she had in her hand—chiefly sticks. She was reprimanded for this habit. Shortly after she began to bite her nails and then to chew her hair. On account of this latter habit her hair was cut short. Her mother tried to cure her of these habits, but never at any time realised that the child was swallowing any foreign bodies.

A CASE OF PERSISTENT PRIAPISM.

BY HERDMAN PORTER, M.B., CH.B. EDIN.,
SURGEON TO THE COTTAGE HOSPITAL, FAVERSHAM.

With Notes on the Surgical Treatment by

R. H. JOCELYN SWAN, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON.

Hinman[1] states that only 170 cases of persistent priapism have been recorded in the whole medical literature and reports two new cases, both in coloured men. He states that the pathogenicity is varied and obscure, and that, as a rule, the priapism responds to no form of treatment. Woolburton[2] reports a case associated with masturbation, and Cowie[3] records one complicating myxosarcoma of the scrotum. G. W. Theobald[4] reports a case associated with myelogenous leukæmia, and Sullivan[5] records one very similar to the case here reported. The following is an account of my case:—

In the early morning of August 27th, 1923, I was called to see an unmarried man, aged 47, who was suffering from persistent priapism and difficulty in micturition.

Previous Illness.—Typhoid fever at age of 28. No history of syphilis or gonorrhœa. At age of 25 he stated that he had a painful erection lasting six to eight hours. No recent accident.

Present Illness.—Began at 5 A.M. on the previous morning, the 26th, when he was wakened by a violent and painful erection, and found that he could only micturate with difficulty. There had been no recent coitus or history of injury to the penis. He went about as usual during the day, including a cycle ride of two miles, the discomfort being bearable. The erection undiminished when he went to bed. As he did not sleep and had increased difficulty in micturition, he sent for me at 5.30 A.M. on August 27th.

Condition on Examination.—Penis in extreme erection, resting on suprapubic region ; any attempt to raise it caused severe pain. Corpora cavernosa very firm on each side, and could be traced easily along the pubic rami as rigid, elongated swellings. Glans penis not swollen in proportion. Dorsal vein of penis not distended; no œdema of prepuce. There was absence of sexual desire. Pulse 78. Temperature 98° F. Examination per rectum revealed nothing abnormal, the prostate and vesicles being normal. Neither liver nor spleen palpable in abdomen, and heart and lung sounds normal. No paresis in legs and knee-jerks; plantar and cremasteric reflexes normal. Cutaneous sensation normal in penile and perineal areas. Pupils reacted well to light. No urethral discharge and no enlarged glands palpable in inguinal, femoral, or iliac groups. Scrotum and testes normal. Urine acid, sp. g. 1025, with a deposit of urates. Albumin and sugar absent.

Blood examination: hæmoglobin, 90 per cent.; red blood corpuscles, 4,700,000 per c.mm.; white blood corpuscles, 12,600 per c.mm.; colour index, 0·9. Wassermann reaction, negative.

Progress and Treatment.—The increasing difficulty in micturition due to the persistent erection was relieved by frequent hot baths, often four times a day; but all treatment was ineffectual in reducing the erection. Pain in the penis, especially at the penoscrotal junction, became increasingly severe, and on Sept. 7th the whole penis was becoming discoloured and assuming a dull livid hue. Fearing commencing gangrene of the penis, I had the patient removed to a nursing home.

At this stage I asked Mr. Jocelyn Swan to see the patient with me, and the following notes are supplied by him:—

"Finding no physical cause for the condition, it was decided to try the effect of cutting off any central stimulus by means of intrathecal anæsthesia. Lumbar puncture was made between the third and fourth vertebræ; the cerebrospinal fluid was clear and under no tension. Intrathecal injection of stovaine and glucose was made. Complete muscular relaxation of the legs with anæsthesia to the level of the umbilicus was obtained, but there was no diminution in the rigidity of the penile erection. It was therefore decided to operate and to incise the crura in the perineum rather than the penile corpora cavernosa. The legs were raised into the lithotomy position, and the perineal surfaces shaved and cleaned with iodine, &c. An incision was made obliquely downwards and outwards on the left side over the pubic ramus and the erector penis muscle exposed and incised; the crus penis was much thickened. This was incised in the line of the wound, when dark, semi-clotted blood slowly exuded. By pressure on the crus and on the penile corpora cavernosa a quantity of the same viscid dark blood was expressed, assisted by the passage of closed forceps into the crus in a forward direction. A similar procedure was adopted on the right side, the same dark blood being expressed, when the whole penis became quite flaccid. A small drainage-tube was passed into each crus and the wounds lightly sutured. No incisions were necessary into the penile corpora cavernosa, the incisions into the crura being dramatically effective in entirely relieving the tense erection."

Subsequent History.—After the operation the penis remained flaccid and the condition was entirely relieved. The difficulty in micturition was also overcome. A moderate amount of bloody discharge continued for a few days, but the wounds healed well, and the patient left the home in 28 days. He has had no return of the priapism, but states that he gets an erection, though the erect penis is drawn to the side. He has had three nocturnal emissions.

Remarks.

I can offer no explanation of the cause of the persistent and painful erection. In the absence of leukæmia, venereal disease, disease of the nervous system, and of trauma, I think that the case must be called one of "idiopathic" priapism in which nothing short of operative interference was of any avail. The cause of the thrombosis in the corpora cavernosa and crura of the penis remains obscure. The immediate relief obtained by direct incision into the crura of the penis in the perineum, followed by the expression of a quantity of dark, semi-clotted blood, points to the treatment to be adopted in future cases, even though true erection may be subsequently affected by the operation. The failure of intrathecal anæsthesia to reduce the erection suggests that the cause must be looked for in the vascular rather than the nervous structures. In some cases, quoted by Jacobson in "Diseases of the Male Organs of Generation," operative measures were directed to the relief of coincident paraphimosis and to direct incision of the penile corpora cavernosa; it would appear that direct attack upon the crura is preferable.

EUGENICS EDUCATION SOCIETY. — On Friday, April 11th, at 8.30 P.M., in the rooms of the Royal Society, Burlington House, Piccadilly, W., Mr. W. T. J. Gun, of the London Society of Genealogists, will lecture on Studies in Hereditary Ability. Major Leonard Darwin will take the chair. Members of the Society and all interested in the above subject are invited to attend.

ROYAL SOCIETY OF MEDICINE.

SECTION OF COMPARATIVE MEDICINE.

COMPARATIVE PATHOLOGY OF CAPTIVE ANIMALS AND MAN.

AT a meeting of this Section held on March 26th, with Sir LEONARD ROGERS in the chair, a discussion was held on the above subject.

Dr. N. S. LUCAS read the opening paper and showed a number of specimens and microscopic sections from animals in the London Zoological Society's Gardens. The subject, he said, was much wider than a comparison of such diseases as tuberculosis, glanders, anthrax, in man and animals, or the relation of small-pox to ordinary cow-pox. The study of this comparative pathology had been so far poorly developed, largely because, so far as he knew, the Zoological Gardens in New York and London were the only ones where post-mortem examinations on the animals which died were systematically carried out and the results recorded. The study was further hampered by the dearth of knowledge concerning wild animals in their normal state; even the process of rumination in domestic animals was but imperfectly understood.

Effects of Captivity upon Animals.

Captivity must exercise a great influence on the lives of animals, sometimes in shortening life, often in lengthening it. In contrast to "a man is as old as his arteries," it could be said that "an animal is as old as its teeth," for when its teeth are worn or otherwise useless it can no longer defend itself or procure food. But the captive animal had its food found and if necessary prepared for it, and could take it without molestation; its life was by this means prolonged. A long course of unnatural diet in captivity would tend to shorten the normal life by lessening the animal's resistance to any infection which might attack it. The natural span of life of various wild animals was not known; by a process of ringing nestling birds and instituting a system of reporting their appearances it was hoped to acquire that knowledge concerning birds, but there were difficulties in the way of applying this to animals. To some animals, petting and attention seemed a necessity; an example of this was the marmoset, which did not live long in institutions; at the "Zoo" the usual life of this creature was about six months, but private owners could keep them in their houses three or four years. Another excellent example was the gorilla.

Diseases of Captive Animals.

In the Zoo there was a practical absence of those diseases which in man and domestic animals resulted from work or the strain of over-stimulated reproduction. Though man suffered from many diseases to which the captive animal was not subject, the captive animal had some which were not fatal to man. In man, inanition was equivalent to starvation, but in the Zoo it meant that the animal continued to eat, but did not receive benefit from the food, was deficient in body-fat, and died. "Senility" in these animals usually meant granular kidney, atheroma, congestion of the lungs, perhaps cirrhosis of the liver. A condition unparalleled in man was the presence of white laminated concretions in the stomach of the porcupine. Analysis of one of three such masses showed an organic origin; it was insoluble in acids, and was apparently made up of smaller amounts of indigestible vegetable substance; there was no sulphur found in it, and no cause for the indigestibility was discovered. Acute specifics, including syphilis and gonorrhœa, were absent in the captive animals; whether they suffered from the anæmias was difficult to ascertain, as it was almost impossible to obtain blood for examination, though leukæmia with splenic enlargement could be diagnosed, and there was one very probable case of this on record. Hodgkin's disease had not been recorded at the "Zoo," neither had acute rheumatism, and endocarditis was very rarely met with, though he had seen a severe case in a monkey.

Malignant disease was moderately rare in these animals, but not because the animals were too young for that disease to manifest itself. Carcinoma of the thyroid was fairly frequent in dogs, and in the Zoo wolves, jackals, and wild dogs had been affected with it; he had seen carcinoma of the testis in a green Australian love-bird. Melanotic sarcoma of the suprarenal occurred in the antelope, and sarcoma of the palate has been detected in an ostrich, and when death eventually ensued there was a secondary growth in the intestine. There had been no case of sarcoma or carcinoma among the apes and monkeys in the "Zoo" for 20 years. The nephritis in these animals was most commonly of the acute kind, but the small white and granular kidneys had also been found. He had never seen a case of cerebral hæmorrhage among these animals. Pleurisy, other than of tuberculous origin, was very rare in them, but empyema was not uncommon. Bronchitis was not an especially common cause of death, but when the lungs became congested the effect on the health was marked, for the animals had but small resistance to pulmonary infection, a fact which Dr. Gaskell, at Cambridge, had amply confirmed. Confined animals also showed but feeble resistance to inflammatory conditions in the alimentary tract, though this was not noticeable since greater attention had been bestowed on cleanliness. Among these animals he had never seen a case of tuberculous meningitis, nor a mammal with a tuberculous joint, but he had seen a dove with both knee-joints involved in this disease. Tuberculous disease of genital organs was very rare; he had seen a case of tuberculous epididymitis in a monkey, and one in a bird.

In conclusion Dr. Lucas said many more years must be spent in accumulating facts on this subject before an attempt was made to build theories, but he hoped others would follow their own special lines of inquiry, and so help to further human pathology from this standpoint.

Prof. G. H. WOOLRIDGE, speaking as a veterinarian, said that the epizoötic diseases were rare in "Zoo" patients mainly because they were kept in semi-isolation, apart from the careful quarantine insisted upon in the case of fresh arrivals. It must be remembered in regard to epizoötics, especially of a catarrhal nature, that they were specific to the particular species; he did not think there was any close relationship between the serious contagious catarrhs of the different types of animals, though many of them had features in common. For example, a disease resembling distemper in the dog was met with in the cat, but there was no evidence of intercommunication; another instance was the influenza of the horse, which was much like that of man, yet here again no intercommunication had been established, though attendants on such horses might have catarrh at the same time. Most of the cases of tuberculosis in the "Zoo" had been found to be due to the bovine strain of the bacillus. It had often been said that the tuberculosis suffered by parrots was of human origin, and that raised the question of danger to the members of a family in which such a parrot had its home. He had no data to offer on that, but hoped some would be forthcoming, because of the importance of the risk. Both tuberculous meningitis and tuberculous arthritis were common in domesticated animals; in most of the cases he had seen it had been congenital, though sometimes the disease was not manifest until a year after birth. The absence of anthrax from "Zoo" animals was due to the manner in which they were kept; in domesticated animals the disease was due to the eating of meal cakes which had been contaminated with hides in the ship or during subsequent handling. There was no doubt about the feeble resistance to lung conditions in these animals, and the bad results were aggravated by the fact that the patients had no power to communicate the fact of their illness until it was very advanced. Horses the subjects of contagious pneumonia often continued to feed for some time, and only a systematic examination of the stud revealed the state of affairs. If a victim of the condition were put to work, the result was always fatal. The comparative absence of malignant disease in wild animals in captivity was a matter of comment, for many of the "Zoo" denizens had lived beyond the age at which domesticated animals developed cancer. In dogs he had seen only two cases of malignant disease in the alimentary tract; one was sarcoma of rectum; in the other secondary growths followed carcinoma in the glands at the anal margin. In domesticated animals nervous diseases were very common, sometimes sufficient to cause death, yet careful post-mortem sectioning gave no result. If careful inquiry were pursued as to this in the dog, it might result in valuable knowledge concerning the human.

Mr. **Humphrey Neame** said a small piece of the third eyelid of a horse was sent to him by a veterinary surgeon to examine. It showed a thickening of epithelium, and he could not decide whether it was papillomatous or carcinomatous, though he suspected the latter. Four months later an ovoid mass three-quarters of an inch long and nearly as wide was sent to him, with the report that it was a recurrence. This was definitely squamous and prickle-celled carcinoma. The two eyes of a kitten sent to him had tuberculosis, mainly of the choroid, the animal having been killed because of blindness. Two months later a second kitten from the same litter, which had been living in a different place, was losing its appetite with lessening visual power, and was sent to him alive. He found tuberculosis in the choroids and disseminated over the body, viscera, and lungs; the brain was not examined.

Dr. **M. J. Rowlands** said he had been informed that the pig was the only animal which could be infected with aviary tuberculosis, and he thought, therefore, that the latter could also infect human beings. He advised that pigs and chickens should not be kept in proximity on farms, and narrated his experiences with chickens fed on foods rich in vitamins. By giving his pigs runs in a wood and feeding them on foods with a vitamin A content he had abolished tuberculosis from one farm entirely. Tuberculous pleurisy he had found to be the commonest cause of death in the pig.

General Sir **John Moore** spoke of an Australian opossum which he had found on the floor of its cage paralysed, and which was found riddled with tubercle, the lungs and pleura being especially invaded.

Mr. **Hamilton Kirk** said that some years ago he was called to treat a parrot, and it was not long before it died from tuberculosis. On inquiry, he found a member of the household had been in the habit of getting the bird to take food out of his mouth. He also spoke of some 80 poultry having died following a tuberculous visitor expectorating in the fowl-run, from which he inferred that they suffered from human tuberculosis.

Prof. **Hobday** expressed his surprise at the comparative absence of malignant disease in "Zoo" animals, as many of them lived to a good old age. With regard to Mr. Neame's remarks, veterinarians recognised that when there was a small tumour on the membrana nictitans it was most likely to be carcinoma, and, however carefully the first growth was removed, recurrence would ensue, and the animal would ultimately have to be destroyed.

Mr. **G. H. Livesey** spoke of the increased lung resistance to disease in animals which could run long distances, like the dog, as contrasted with the cat, the latter showing very little power to fight a lung infection. Apart from traumatism, he believed every case of pleurisy was tuberculous. Often tuberculous disease in the cat was first seen in the eye—i.e., keratitis, or detachment of retina, or dislocation of the lens probably preceded general emaciation. Mr. Henry Gray had declared that of all birds the parrot was most liable to have human tuberculosis.

The **Chairman** said post-mortem examination had now been instituted on animals which died in the Calcutta "Zoo." Aspergillus affecting the ears was very common in the hot rainy season in India. He referred to a discussion to be held on tuberculosis as met with in medical and veterinary practice as one of obvious importance. He agreed that the variety of tuberculosis affecting the monkey seemed to be the human.

Dr. **Lucas** briefly replied.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A meeting of this Society was held at the rooms of the Medical Society of London on March 28th, Colonel L. W. **Harrison**, D.S.O., the President, being in the chair.

Gonorrhœa: Infection by Secondary Organisms.

Colonel E. T. **Burke** opened a discussion on this subject, confining his attention to the male urethra. He said knowledge of the bacteriology of the urethra in general, and of the gonococcus in particular, was not yet so accurate as to warrant dogmatic statements concerning secondary infection. The subject bristled with problems for the pathologist and clinician; truth was not always to be found at the bottom of a test-tube nor on the microscope stage. Sometimes the clinician accepted without question laboratory findings even though they seemed to contradict clinical experience. Laboratory findings had again to pass through the ordeal of clinical experience before acceptance. Where experiment ended speculation began: it was the finger-post to further research.

Symbiotic and Parasitic Organisms.

The view that the healthy body was sterile he regarded as erroneous; it was responsible for the conclusion that whenever the bacillus x was obtained from the tissues or fluids of a sick body, the patient was suffering from x-itis, and treatment was focused on the elimination of bacillus x. Should there be no symptoms, he was designated a "carrier." He agreed with Mr. Frank Kidd in regarding the body as a "bacterial sponge," that certain organisms were naturally symbiotic to the body, and that periodically, and without causing disease, these invaded the blood-stream. Such a conception was necessary to an understanding of the processes of infection and immunity. Some of the organisms, such as the Neisserian gonococcus, were not symbiotic, but parasitic, and their entry aroused resistance, shown first by inflammation. Some of them, such as the pneumococcus, *B. influenzæ*, *B. diphtheriæ*, may become naturalised citizens, losing, or concealing, their undesirable characters. The normal, or naturalised, bacterial inhabitants of any part of the body might, under some stimulus or some indiscretion on the part of the patient, "see red" and become offensive. Conversely, such might settle down and even function for the common good.

Among the organisms which had been recovered from the healthy male urethra were three varieties of staphylococci, diphtheroid bacilli, micrococcus subflavus, streptococci, *B. coli*, and Gram-negative diplococci, not gonococci. He did not agree that any organisms found in the urethra had entered by the meatus; his view was that the organisms which lived on the skin and mucous membranes and in the bowel entered the blood-stream via the lymphatics, and were again got rid of by the various glands, such as the kidney. This intermittent invasion of the blood-stream was the basis of our immunity to these organisms, and it was only when the general or local resistance was lowered that there occurred a rigor, headache, lumbago, or osteomyelitis. As the normal urethra had a bacterial flora, he did not see how an aseptic urethritis could occur. When the urethra was injured, the flora found in the injured area an added stimulus to growth and activity, their character changed, and they took on an enhanced virulence. The gonococcus might cause the initial damage, but even after the disappearance of that organism the damage might to a certain extent persist, and on it the other organisms might flourish. If local treatment was pushed too vigorously, this, by increasing the urethral damage, might do more harm than the actual presence of microbes. The possibility of organisms which were saprophytic to the prepuce, glans, and fossa navicularis being driven up the urethra and flourishing there was a very remote one.

Polymorphism in Bacteria.

With regard to the gonococcus itself, owing to the readiness with which it "digs itself in," it seemed hopeless to expect to eradicate the disease completely by local measures alone; the entertainment of such a hope seemed to be responsible for the disease becoming chronic and for the supervention of secondary infection. He believed that the main element of success in the irrigation treatment in the case of the male was that of the mechanical cleansing, but until chemical agents were available which were both fatal to the gonococcus and harmless to the cells of the urethral membrane, the irrigation treatment would be fraught with much danger in the hands of those who aimed at a rapid cure. Vaccines, sera, the injection of some of the metallic elements in a colloidal state, seemed to be on the correct lines; the important thing was to discover a colloid which had a distinct affinity for the gonococcus. Frequently the bacteriologist was unable to recognise the gonococcus on morphological grounds; the organism in culture showed a marked tendency to deviate from the normal in size, shape, grouping, and staining properties. This could be seen in a 24-hour culture, and at the end of four days the culture would exhibit very few normal gonococci. There thus seemed to be a gradual devolution from the Neisserian gonococcus to the simple coccus, or an evolution in the opposite direction. Many of these variant forms did not differ materially from those found in urethral smears and labelled "secondary organisms." It was very important to know whether these organisms, in whole or in part, were really metamorphosed gonococci, and whether, when receiving the needed stimulus, they would again develop the characteristics of the typical gonococcus. From prolonged residence in the urethra the latter may markedly diminish in virulence, but on conveyance to the healthy female genitalia may resume their pristine malignancy, and the reinfection thence of the infecting male may re-establish the virulent disease in him. Possibly the Neisserian gonococcus was a descendant from one of the normal inhabitants of the genital passages.

Dangers of Over-Treatment.

He emphasised the fact that there were great difficulties in the way of treating gonorrhœa, and laid stress on the importance of early treatment and the avoidance of over-treatment. He believed that, given proper treatment, secondary infection should not occur, and that the main cause of the latter was over-treatment. Gentleness in treatment was necessary, and the urine should be rendered dilute, alkaline, and copious, non-irritating alkaline fluids being used. The protective forces must be stimulated by vaccines. When a secondary infection had occurred, an attempt to beat it out was usually futile and would establish a vicious circle, for it devitalised the urethral mucous membrane and seriously lowered the resistive power. A six months' cessation of all treatment would sometimes prove more beneficial than anything else. The urethra should not be tortured in an attempt to sterilise it.

Serum Treatment.

Miss **FRANCES IVENS** related her experiences at the Morley Hospital, Liverpool, where most of her patients were "respectable married women." In the out-patient department there the incidence of gonorrhœa was 14 per cent., while 24 per cent. of the cases admitted for operation had the infection; 30 per cent. were sterile. Latent cases exhibited a tendency to become acute at the puerperium, or after such an operation as dilatation for sterility. She questioned the wisdom of keeping the woman in ignorance of the nature of her disease. She favoured confidential notification of the disease to the public health department. Her experiences in the war in France brought her into contact with the work of the Pasteur Institute, and what she saw encouraged her to try the effects of a gonococcal serum when she returned to her work in Liverpool. When she resumed there, in 1919, she found that the incidence of gonorrhœa among the patients at the hospital was even higher than before, in spite of the propaganda work which had been done and the clinic which was founded. She used Nicolle's serum on 50 patients, mostly cases with salpingo-oöphoritis with pus formation. Used on packs for the vagina the results were good, but it was not an economical method. She opened both tubal and ovarian abscesses, then injected 10 to 20 c.cm. of serum into the tubes, and left the residue in Douglas's pouch. Rectal salines were also given. In later cases she used the serum subcutaneously, in combination with surgery as before, and she was more satisfied with this method than with any other. Sodium chloride had been found to have a protective action against disturbances following the injection. She did not use it intravenously, as she had seen fatal anaphylactic shock follow it. The after-history of the patients so treated had been very satisfactory; several had since borne children. Though this serum treatment was curative it could not be regarded as prophylactic when the patient continued to be exposed to reinfection. She narrated some cases in which the treatment in severe cases had yielded excellent results. At present there did not seem to be an antitoxic serum available. MM. Dubois and Minet suggested that efforts should be made to obtain serums very rich in antibodies, and the speaker thought much progress would follow the preparation of an antitoxic serum which could be used locally.

Dr. **MARGARET RORKE** agreed with Colonel Burke concerning the morphological changes seen in gonococci; sometimes they looked more like staphylococci. If the patient was in fair health, then, apart from the menstrual period, the gonococci seemed to subside in a remarkable way.

Dr. **T. G. WRIGHT** spoke of cases, rebellious to ordinary treatment, which had cleared up under diathermy.

Dr. **FOWLER WARD** said that, with regard to the male, if he got a negative result with the urethroscope and after prostatic massage he regarded the case as cured. The real test, which could not be instigated clinically, was when the man could practise coitus without imparting the disease to his healthy partner.

Dr. **H. BARDSLEY** said he had found that cases of secondary infection cleared up very well with prostatic massage and the injection of autogenous vaccines. In chronic gonorrhœa he did not think the prostate was usually sufficiently treated.

Dr. **B. B. SHARPE** agreed that as the gonococcus might gradually assume different types the difficulty of diagnosing when an infection was secondary was enhanced. He referred to the stubborn nature of sago-grain urethritis in patients who had not gonorrhœa nor a history of it. Cases of diphtheroid infection in children were also very resistant.

Dr. **A. H. HARKNESS** spoke of his success in washing out the urethra with a 1 in 4000 oxycyanide of mercury solution or potassium permanganate.

Dr. **Z. KADINSKY** said he had not had a case of secondary infection in his cases since he carried out irrigation with plain water. He agreed that cessation of treatment was beneficial in cases of secondary infection.

Mr. **C. MYERS**, alluding to the statement that organisms were always present in the male urethra, said he was constantly receiving hospital reports that there were no organisms, but only a few epithelial cells, and asking that prostatic massage might be done.

The PRESIDENT said he believed there was a growing scepticism concerning pathologists' reports, and when he encountered this he asked whether the specimens had been taken properly. Often they were taken in such a way that the pathologist could do nothing with them. There was certainly room for more coöperation between pathologist and clinician. He had often been in doubt whether the Gram-negative bacilli on a slide were gonococci or not; for that reason he was inclined to adopt the cultural method. If the doubtful organism could be grown on an ordinary medium it went far to negative it being gonococcus, as the latter was very particular about its medium. He did not believe that secondary organisms were natural inhabitants of the whole urethral canal, but multitudes could be found in its first centimetre. In many cases saprophytes grew and set up a mild urethritis because the ground had been prepared for them by the gonococcal infection. Strong enough chemicals might not be used in treatment to turn them out. Stronger solutions than 1 in 4000 oxycyanide of mercury, short of caustic, might succeed. He had had success with 5 per cent. mercuriochrome. Failure to take aseptic precautions was responsible for many cases of secondary infection. Diathermy was very effectual in clearing up prostatic infection.

Reviews and Notices of Books.

MENTAL DISORDERS.

An Introduction to the Study of Mental Disorders. Second edition. By FRANCIS M. BARNES, jun., M.A., M.D., Associate Professor of Nervous and Mental Diseases in the St. Louis University Medical School; Neurologist to St. Mary's Hospital. London: Henry Kimpton. 1923. Pp. 295. 18*s.*

THE outward features of mental disease receive here less attention than is usually expected in a students' manual, and practically no illustrative cases are described. An unduly large amount of space is devoted to the theoretical considerations on which the practice of psychiatry is based, and these sections are written in such a way that they could well be compressed without detracting from their value, or reducing the amount of information they contain. There is, in fact, a singular lack of positive and detailed information throughout the book; the section on paranoia, for example, contains no description of this disease whatever, but consists merely of a discussion as to the proper scope of the term, a well-worn controversy with which a student ignorant of the very nature of the disease need scarcely concern himself. The remarks on treatment are very brief. No mention is made of the use of alcohol in delirium tremens. No attempt is made to adjudicate on the sphere of modern psychotherapy. The author's simplified classification of mental disorders is more intelligible than many that have been put forward. Some of the words and expressions used are unfamiliar; if brevity be the excuse for "pathologic," why "symptomatologic" rather than "symptomatic"?

Dr. Barnes's book is intended primarily as an adjunct to his own clinical teaching at St. Louis, Missouri. Presumably his students are able to gain a considerable amount of clinical experience, for without this they are unlikely to derive much benefit from his book, which is indeed more suitable for advanced readers.

FIFTY YEARS OF MEDICAL PROGRESS, 1873–1922.

By H. DRINKWATER, M.D. Edin., M.R.C.S. Eng., F.R.S.E. London: H. K. Lewis and Co., Ltd. 1924. With 37 illustrations on 35 plates. Pp. 183. 10*s.* 6*d.*

IN the preface to this record of 50 years of medical progress Dr. Drinkwater reminds us how many subjects that in 1873 were shrouded in seemingly impenetrable mystery have yielded up their secrets. In 1873 very little was known regarding germs in relation to disease; in fact, the term bacteriology had not been introduced. In surgery the carbolic spray was in the height of its popularity, while since X rays had not been discovered the treatment of fractures rested on a less certain basis. During the period under review the whole aspect of medicine has been changed. Diseases (for example, malaria and yellow fever) which have been widespread scourges have been partially, and in some places completely, eradicated; surgical operations that were definitely stated to be unjustifiable are now performed successfully every day in the great hospitals all over the world; parts of the body that were looked upon as vestiges of some former age are now known to be of importance, the net result being the relief and prevention of much suffering, the conferring of immunity to certain diseases, and an increase in the expectation of life by several years.

The alphabetical arrangement of the subject-matter is commendable, but since dates form the subheadings it is unfortunate that discoveries and advances are not chronicled in orderly sequence. It is disconcerting, for example, on. p. 93 to find a series of haphazard paragraphs in the order 1881, 1891, 1877, 1874, 1884, 1910, 1876, whereas with a little care in arrangement they would have told a connected story. There are a few regrettable gaps. Under diabetes a reference to the discovery of insulin is to be found, but the most recent entry under cancer is 1903. The book will be useful as a work of reference, and to revive the failing heart of pessimists who see only the fields untilled in medicine and are blind to the progress already made. Among the illustrations are pictures of 25 men whose original work has marked special stages in the progress outlined.

HAND-ATLAS OF HUMAN ANATOMY.

Fourth edition in English. By WERNER SPALTEHOLZ. Edited and translated from the seventh German edition by LEWELLYS F. BARKER. With a preface by FRANKLIN P. MALL. London and Philadelphia: J. B. Lippincott Company. 1923. In three vols. Pp. 902. £3 10*s.*

Spalteholz's Anatomy requires no introduction to the English student of anatomy, and his congratulations, as well as those of all who may have occasion to use this beautiful edition, are due to Prof. Barker and all concerned on the results of their efforts. Even one who is not by any means convinced of the value of "atlases" must perforce praise the exquisite illustrations which make up the bulk of the volumes. It would be but captious criticism to point out certain little details in which we cannot see eye to eye with the original delineator, but the attention of the editor might justly be drawn to the large coloured representation of the fundus oculi. It cannot be said definitely that the condition shown is an example of cerebro-macular trouble, but there can be little doubt that the darkly pigmented macula is not normal, but degenerative; in many respects it would be of advantage to substitute for this figure another fundus in a simpler style. The late Prof. Franklin P. Mall, who wrote the original English preface, was a declared believer in anatomical atlases. Our faith is not so clear and unquestioning. But no one could have hesitation in putting this great production among the books that count.

PAPERS AND ADDRESSES IN SURGERY.

By R. HAMILTON RUSSELL, F.R.C.S., Associate of King's College, London; Consulting Surgeon to the Alfred Hospital, Melbourne. Melbourne: Allen Grant. 1923. Pp. 452.

THIS is a selection from the author's writings of the last 25 years. Various subjects are dealt with, but two stand out as particularly associated with his name. They are the origin of hernia and the treatment of fractures. It is interesting to read again the steps which led to the evolution of the saccular theory of hernia. Much of the reasoning we know now to be sound, but the acceptation of the hypothesis for the origin of femoral hernia without reserve is rendered difficult by the consideration of facts brought against it by other observers. Further study is needed before surgical opinion can become unanimous on this subject.

The same originality in outlook is evident in Mr. Russell's observations on the principles which should govern the treatment of fractures. He insists upon the necessity for the limb being in the natural position of rest, for in this position alone are the muscles so disposed that there is no tendency to incorrect alignment. His methods of treating fractures of the femur and leg are appealing in their simplicity and it would seem in their effectiveness. Yet their application is an art and requires daily supervision. It is much to be desired that the author's advice to withhold passive movements for fractures near joints, especially in children, should be more widely adopted. There is an original method for dealing with intractable stricture of the urethra in another section of the book, and an account of the first recorded case of the removal of a pin from the lung by open thoracotomy. The inspirations which have guided the author through a strenuous surgical life may be gathered from the Presidential Address in Surgery at the 1914 Australasian Medical Congress. It is a delight to read, as it must have been a pleasure to hear.

Urology.

Endoscope operatoire des voies urinaires. By E. Papin, Ancien Chef de Clinique de l'Hôpital Necker, Chirurgien adjoint de l'Hôpital Saint-Joseph. Paris: A. Maloine et Fils. 1924. Pp. 110. Fr.26.

This manual treats of operations which can be carried out upon the posterior urethra, bladder, ureter, and kidney through the cystoscope and cysto-urethroscope. All procedures described are done through prismatic cystoscopes, the direct instruments being only referred to here and there. The author gives a very good description of the various established endovesical procedures, and makes frequent reference to the work and methods of American surgeons. He does not seem to be acquainted with the ingenious retrograde cystoscope of Mr. Swift Joly, by means of which lesions at the bladder neck can be reached. A strong advocate of endoscopic methods, he yet realises their limitations, and recommends resort to open operations when necessary. His treatment of the tuberculous bladder after nephrectomy, by diathermy, is apparently new, and seems to give good results. The numerous diagrams in colour and black and white are beautiful representations of appearances seen through the cystoscope, and depict very clearly the methods employed.

Clouds and Smokes.

The Properties of Disperse Systems in Gases and their Practical Applications. By William E. Gibbs, D.Sc., Chief Chemist to the Salt Union, Ltd., Liverpool. With a Foreword by Sir Oliver Lodge, F.R.S. London: J. and A. Churchill. 1924. Pp. 240. 10*s.* 6*d.*

We shall probably not be content to neglect clouds and smoke in our big cities as we have in the past; they are too costly in two respects—human life and coal. It is known that town fogs are due to incomplete combustion of coal, mainly in the domestic grate; with improved methods of burning we should still have mists, but, owing to the greater temperature of towns, these would probably not be so frequent as in the country districts. Legislation in these matters is very slow here; not so in America, for Pittsburg has apparently cleared its reputation of having the worst atmosphere in that country, and report now has it that the air of the town is as clean as that of Bath. The first six chapters of the book are devoted to the methods of formation and the general physical and chemical properties of aerosols. The remaining five chapters are devoted to the way in which fumes and dirty gases are treated industrially; to dust explosions, their cause and method of prevention; to the preparation of substances in a very finely divided condition; and the use of smoke in warfare. Some account is given of the meteorological conditions affecting the presence of dust and water particles in the atmosphere.

In his foreword Sir Oliver Lodge emphasises the significance of the subject of smokes and clouds in civil life. We can pass on with confidence the commendation he gives to this book, for an extraordinary amount of well-handled information is here got together. It is one to which reference can safely be made on a subject of growing importance to the public health.

The Medical Annual.

A Year-book of Treatment and Practitioner's Index. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. 1924. Pp. 616. 20*s.*

The appearance of the Medical Annual each year is welcomed not only by practitioners who have little time to keep abreast with current literature except through its good offices, but also by those who read widely on certain limited lines and have learned to rely on this publication for a summary of the year's work, and for indications of progress in directions unfamiliar to them. Especially do practitioners resident in distant parts of the world appreciate the Medical Annual and the beautiful coloured plates with which it is illustrated. The information given is collected and arranged in assimilable form, and the several articles, though brief, are sufficiently critical in tone to guide the reader to a sense of the value of new work. The treatment of diabetes by insulin naturally looms large in the 1924 volume. A discussion of the history of the experimental investigations into the ætiology of disseminated sclerosis appears to be exceptionally complete. It is pointed out that in this, as in many other diseases, it may happen that a spontaneous remission coincides with some particular method of treatment, which may thus gain unmerited credit as a therapeutic agent. This attitude of reserve in assessing the value of treatment is happily growing with the better scientific training of the medical student. Practitioners may rest assured that in this manual no undue praise is given to new remedies without regard to the circumstances of their trial.

Popular Bacteriology.

Fighting Foes too Small to See. By J. McFarland, Professor of Pathology in the University of Pennsylvania. Philadelphia: F. A. Davis Company. 1924. With 64 illustrations. Pp. 309. $2.50.

This is not about pride and covetousness, but about microbes, and it is a pity the author was not frank enough with the audience he desires to reach to say so. It is the outcome of a series of popular lectures on bacteriological hygiene given in Philadelphia, and is but a moderately successful attempt to instruct a lay audience how to make practical use of modern parasitology in an understanding way. Such popularisation is never an easy thing to do well, and Prof. McFarland fails in two different ways. In the first place, he does not realise how completely his own mental and verbal phraseology differs from that of people who have had no training or experience in the natural sciences. And as a result technical words and phrases slip into the narrative more frequently than they should; we do not wonder that one publisher declined it on that ground. And in the second place, the author falls to the temptation of making his readers gasp and wonder at the amazing things he has to tell. Rather more than a quarter of the book is occupied with plague and sleeping sickness—travellers' tales which are miraculous indeed, but hardly within the picture. The laymen neither wants nor needs this; he wants just the same plain truths about microbes that the elementary medical student wants, only they must be expressed in terms he can understand.

Apart from these defects, the book conveys a good deal of useful information which should contribute to the healthiness of its readers. It is too bacteriological and does not lay enough stress on the fundamentals of sound hygiene—the personal and communal common-sense decency and cleanliness in which Chadwick and Simon and their companions laid the foundation-stone of modern hygienic progress. Washing, indeed, seems hardly to be mentioned as an anti-microbial procedure; it is, however, detailed as one of the incidents of life which brings microbes into contact with the body—and this in a country where every big hotel will presently advertise that each bedroom has two bathrooms. Perhaps if washing with sterile water were more general, Prof. McFarland would allow kissing (p. 88), and let us go on taking off our gloves before we shake hands (p. 93). It is, frankly, directions like these which are apt to bring bacteriology into something like popular contempt. The technical details seem to be accurate. "Doubtless a rat-flea can live for a time upon any blood" (p. 251) can hardly be true, since some rat-fleas will not feed upon, e.g., man. On the same page Martin is disguised as "Roger." Dr. Bastian's name is mis-spelt (p. 30). The description of Lister as a "Scotch surgeon" needs qualification.

JOURNALS.

MILITARY SURGEON.—The February number of this journal presents the first of a series of articles on the medical problems of the German army in the late war written by Germans. This month's article, by Colonel Dr. Waldmann, is on Shelters and Water-supply in Defensive Battles, which are characterised by the immense accumulation of men and stores in a very restricted area, with losses very heavy and replacements difficult. The urgent needs in that situation are shelter and water. As to shelter, soldiers must be crowded; the Germans made transportable barracks (huts), each hut holding 48 men, with 200 cubic feet for every man; these were found satisfactory for supports. Huts should be in woods, for shelter from the winds and for concealment. Caves make good shelters. In dug-outs, where 125 cubic feet is the maximum, ventilation is of great importance, and is best secured by a fire, which may have to be of charcoal, lest smoke attract notice from the enemy. Trenches and dugouts must be drained, best to a sump pit; water will find its way here and so will heavy lethal gases; chloride of lime spread about will destroy any mustard gas. Humidity was found more trying than carbonic acid (even 10 per cent.) in these underground passages. Carbonic oxide was watched for with palladium chloride papers. During bombardments latrine buckets had to be taken into dug-outs and emptied during intermissions. Cresol, sprayed in watery solution from a syringe, was found a good deodorant for bodies lying in between the lines. Pill-boxes (of reinforced concrete) had so little ventilation, their atmosphere was so moist, that service in them was dreaded, but they fulfilled the essential requirements of hygiene, and the men could still fight and fight well in them. Colonel Waldmann says that at last even hygiene fails and only iron determination and contempt of death keep men going. The best protection against epidemics is clean water, but the piped supply to the front line breaks down in battle, which cuts the pipes. So underground cisterns were made, wells were developed, even up to the second-line trenches, village wells being cleaned with chloride of lime; in action, water was carried forward by water wagons on field railways, or on men's backs, or had to be dropped by airmen. A filter was put in each man's canteen, chlorination then killed infection and boiling got rid of lethal gases, except arsenic and picric acids. It appears that the German methods were very like those that solved the same problems for ourselves.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XIV.—PRESCRIBING FOR PANEL PATIENTS.

BY LEONARD SHOETEN SACK,
BARRISTER-AT-LAW; JOINT AUTHOR OF "MEDICAL INSURANCE PRACTICE."

We now prescribe, like doctors in despair.—*Dryden.*

THE provision of medicines for panel patients has given rise to much bona fide misunderstanding and to much malicious misrepresentation. The doctor and the insured person have been equally concerned. There is a psychological reason for the patient's suspicion. The "bottle of medicine" still remains an almost sacrosanct plebeian institution. Medical treatment without it is regarded as either mean, inefficient, or neglectful. Health education has not yet persuaded the commonalty to accept without resentment a treatment of self-denial as a substitute for an intemperate indulgence in physic. Anything which tends to depreciate the contents of the medicine-bottle is therefore a factor of great influence on the minds of the insured population.

The widespread misconceptions on the part of many insurance doctors is also explicable. The varying provisions of statute and regulations, and the varying practices at one time current in different areas, have no doubt had much to do with them, but the trouble mainly centres in the novel method of control which the regulations have set up in connexion with what is felt by so many doctors to be essentially a matter for private professional judgment.

The subject is one of such importance both to the reputation and practical efficiency of medical benefit that an elementary restatement[1] of principles will, it is hoped, be forgiven.

Basic Definitions.

There are three fundamental definitions. Section 8 of the National Insurance Act, 1911, defines medical benefit as "medical treatment and attendance including *the provision of proper and sufficient medicines. . . .*" This definition is amplified by the medical benefit regulations. Schedule I. includes among the insurance doctor's duties the prescribing of "*such drugs . . . as are requisite for the treatment of any patient,*" while Section 37 (dealing with excessive prescribing) sets up, as the standard of character and quantity of the medicines, "*what is reasonably necessary for the adequate treatment*" of the insured person.

It is of the first importance that these definitions should be kept clearly before the mind. They are the authoritative statutory definitions to which the doctor can appeal; any departmental decision and any administrative or executive action on the part either of the Central Department or of the local committees which did not accord with them would be ultra vires and could be successfully contested in a court of law.

In fact, however, the Ministry of Health do not appear to have attempted to limit improperly the scope of these definitions or to restrict unduly the professional judgment of the doctor in applying them. Emphasis has repeatedly been given to the principle that the doctor is not only entitled but required to prescribe the medicines—whatever may be their cost—which are, in fact, necessary for the proper and adequate treatment of the patient. On a broad view of the question it could not be otherwise. One has only to consider the list of drugs and appliances for which special payment is made to doctors who themselves supply medicines at a capitation rate. The list includes vaccines, serums, peptone and glandular preparations, and insulin. It is not reasonable to suppose that a scheme, which admittedly allows the provision of these preparations whenever they are actually necessary for the treatment of the patient, should require or encourage the doctor to deny other and cheaper necessary medicines.

---

[1] For purposes of brevity reference is made only to medicines, but the principles apply equally to the ordering of such appliances as have been prescribed by Regulation. The discussion does not apply to doctors who themselves supply drugs and appliances at a capitation rate—their main concern is as to the adequacy of the capitation rate.

Checking Extravagance.

The misunderstandings which have overclouded the basic principle appear to be traceable to the provisions of the regulations for dealing with cases of "excessive prescribing." The whole principle of control in this respect, and the detailed machinery which has been set up to secure that control, are criticised on three main grounds: (1) that they are unnecessary; (2) that they constitute an unjustifiable and improper interference with the doctor's professional judgment; (3) that the mere possibility of surcharge constitutes, in effect, a continual menace which has justified the belief in an unduly restricted choice of medicines for insured persons. An examination of these three criticisms is perhaps a convenient way of exploring the subject.

In considering whether there is a need for any sort of check or control, it is necessary to recall that one is dealing with a scheme of insurance. No insurance policy can offer unlimited benefits for limited premiums; the defined premium covers a defined risk. The premiums paid on the National Health Insurance "policy" cover, inter alia, the provision of whatever medicines are reasonably necessary for the adequate medical treatment of the policy holder—i.e., the insured person. This is clearly something different from an unlimited supply of medicines or medical preparations, irrespective of their actual need for treating the particular illness. In the case of O'Neill *v.* Middlesex Insurance Committee (1916, 1 K.B. 336) Mr. Justice Rowlatt thus interpreted the position:—

> "The Act is worked upon a scheme that there is to be a fund to provide for these drugs as well as to pay the doctors, and it is obvious that there is a limit to the amount available for that purpose. The duty of prescribing for any patient necessarily involves that the prescription must be reasonable according to the resources available for pay. . . . there must be a duty on a panel doctor not to be extravagant or reckless in ordering medicines which are unnecessarily expensive."

Or, as the principle was stated by the department, the doctor "must prescribe for his insured patients whatever drugs are necessary for adequate treatment, however costly they may be, but on the other hand, he must have due regard to cost and not order the more expensive preparations for purposes for which the less expensive will serve equally well."

Accepting, as one must, this necessary limitation to the benefit provided, some sort of control would seem to be unavoidable. The insurance scheme affects 15 million persons; for England alone 36 million prescriptions are now written in the course of a year at a cost of close on 1½ million pounds, and the number is steadily increasing; 15,000 doctors are entitled by writing prescriptions to make heavy charges on the insurance funds without affecting their own remuneration. If the actuarial calculations underlying the insurance scheme are to be verified, some check must evidently be put upon the giving of benefits which are not covered by the prescribed premiums.

The Machinery of Control.

Granting the need for some form of control, does the existing machinery involve undue lay interference with the professional judgment of the doctor? Let us examine the skeleton construction of that machinery. All National Health Insurance prescriptions are priced at the Pricing Bureaus which have been set up at various centres. In the course of this work certain tables of averages are prepared, affecting the lists of individual doctors, or given areas. These figures are submitted for scrutiny to the Minister of Health. If the scrutiny reveals in the case of an individual doctor an average cost per prescription considerably in excess of the general figure for the area, further details as to the individual prescriptions affected are obtained from the bureau. If this further information still suggests an unexplained and considerable excess above the average, the Ministry take initial action by bringing to the doctor's notice, through the regional medical officer, the facts which suggest extravagant prescribing. The doctor can then either make an oral explanation to his regional medical officer (who will call upon him—accompanied by a representative of the panel committee, if that committee so desire) or he can send a written reply direct to the Minister. Often the matter will not go beyond this stage. If the prima facie case of extravagance seems to require more formal investigation the whole matter is referred to the panel committee—a body, be it remembered, consisting solely of doctors, at least three-fourths of whom are panel doctors. *It rests with the panel committee alone to decide the crucial question whether there has or has not been extravagance;* and before that committee can arrive at this decision they must give the doctor an opportunity of appearing before them or of submitting a statement. The subsequent functions of the insurance committee and of the Minister are respectively to recommend and decide the penalty, if any, to be inflicted if the panel committee finds that there has, in fact, been extravagance. The doctor may appeal against the panel committee's decision to a court of independent referees of whom one must be a doctor; the Minister can similarly refer the case to independent arbitrators if he is unsatisfied with the action of the panel committee. Further, the Minister may permit a panel committee to make the initial investigations of statistics on which the prima facie case is established.

The essential decision as to whether there has been extravagance is thus in the hands of the panel committee or of an independent court of referees on which the profession is represented. So far as there is interference with the professional judgment of the doctor it appears to be an interference sanctioned by members of his own profession.

Personal Variations.

The general opinion or practice of the profession does not, however, necessarily determine the question, for it has on several occasions been recognised that the personal element in prescribing is a material consideration. The following official dicta may be quoted:—

> "In interpreting the term 'reasonably necessary' . . . allowance must be made for the personal element. It is clear that if insurance practitioners are to retain the independence of judgment that is necessary for the best treatment of their insured patients, rigorous conformity with the view of the majority of the profession or of a Committee of the profession must not be required of them; and, that the progress of medical science may not be checked, scope must be allowed for the exercise of initiative and for suitable experiment. The enforcement of stereotyped methods and standards of prescribing would be prejudicial both to the immediate interests of patients under treatment and to the ultimate interest of insured persons generally. . . . Just as one workman can use a tool better with a handle of one shape and another with another, so it is desirable that, within reasonable limits, a doctor should be allowed to follow methods of treatment which are most congenial to him. . . . .
>
> The question is . . . not to be determined by the test of rigid formulæ, but by the application of common sense to the facts of the particular case, which must be viewed as a whole."

Similarly, consideration is given to the particular circumstances of the practice. Thus, the average cost per prescription will probably be greater in the small practice. Or again,

> "If the patients of a practitioner considered collectively require a more than usual amount of treatment, or are particularly liable to illnesses requiring treatment of a more than ordinarily expensive kind, or if he has a run of cases of a particular kind requiring specially expensive treatment, all these facts must be taken into account in interpreting the meaning of a high average cost of prescribing."

On the other hand, it has been established that the adoption by the doctor of similar methods of prescribing for private patients does not in itself afford proof that there has been no extravagance as regards panel patients. Neither is the preference of the patient for a particular medicine regarded as providing in itself a sufficient ground for relieving the doctor of the responsibility to decide what is necessary.

Excessive Prescribing.

There remains the criticism, undoubtedly of considerable influence, that the mere existence of an elaborate machinery for penalising excessive prescribing places an undue restraint on the writing of prescriptions. A brief survey of the main principles on which cases referred to the Minister have been determined may assist in assessing the measure of apprehension which is justified.

One group of cases deals with an unnecessarily high cost of the medicine or of some of its ingredients. This may occur through the unnecessary use of patent medicines or proprietary preparations where an equally efficacious but less expensive B.P. preparation is available. Proprietary preparations are not, as a class, disallowed. "We recognise," the department have said, "that proper allowance for the needs of exceptional cases might justify the use of a proprietary article in a certain number of cases." The question to be determined is "whether it was necessary for the adequate treatment of the patient that preparations made by particular manufacturing firms should be used instead of less expensive preparations suggested in the B.P. which are ordinarily employed by medical practitioners for the same purpose." Many proprietary preparations have notoriously no greater therapeutic value than cheaper B.P. preparations and in such cases it seems not unreasonable to say that there is neither need nor excuse for a routine use of the proprietary article.

The question of unnecessarily expensive B.P. preparations is governed by the same considerations. Where, through a routine prescription of particular combinations or a mere indifference to cost, costly ingredients are included without improving the therapeutic value of the medicine with reference to the particular patient for whom it is prescribed, a legitimate case for criticism would seem to lie.

Again, an excessive use of flavouring agents may constitute extravagance. In one case where the flavouring agents were six times as costly as the active drugs, the panel committee :—

> "did not contend that sweetening and flavouring agents have not a proper place in the composition of some remedies but that those preparations cannot be placed in the same category, therapeutically, as what they described as 'active' drugs, and that a reasonable moderation should be observed in using them."

Instances have arisen where an expensive medicine is prescribed on the recommendation of a consultant. Here the view of the department is that the consultant's recommendation is clearly a matter of which account must be taken in determining whether the medicine was reasonably necessary, although obviously extravagant prescriptions could not be justified solely by reference to the consultant's advice. Cases have, again, occurred where an unnecessarily high dispensing fee has been incurred. The unnecessary prescription of a preparation in powder or tablet form has, for example, been held to place an unjustifiable charge on the drug fund.

Finally, there is extravagance by unnecessary frequency of prescriptions. Here again, so far as recorded cases go, the abuse has ordinarily been obvious where a penalty has been inflicted. Two typical cases may be quoted. In one case 1 lb. malt and oil was prescribed on the 9th, 15th, 22nd, and 30th of a month, the dosage ordered being such that each prescription should have lasted 17 days ; in the other case eight prescriptions given between the 1st and 25th of a month accounted for a 60 days' supply of medicine. Few doctors would object to such cases being the subject of inquiry and control. More difficult is the problem of the steady increase in frequency throughout the country ; but this is a matter to be dealt with on the basis of broad policy rather than of individual disciplinary action.

The Position Summarised.

A layman must necessarily draw conclusions on this subject with great reserve. On the whole, however, it seems that the cases where surcharge has been upheld by the Ministry are, generally speaking, not such as would regularly occur in the practice of the reasonably careful practitioner ; neither do they appear to afford ground for undue apprehension or for an excessive caution in withholding medicines from insurance patients. The subject has been so overlaid with misunderstanding that an exaggerated complexity has been attributed to it. So far as the doctor is concerned, there seems to be only one standard and one question to be answered : "Is the medicine or preparation which I propose to prescribe reasonably necessary, as regards character and quantity, for the adequate treatment of the particular patient for whom it is to be prescribed ?" If the answer is in the affirmative, the statute and regulations definitely sanction the prescription. It may be said that this is not an easy standard to apply. But is it not, after all, precisely the standard which is daily applied by the many doctors who are supplying medicines at a capitation rate of payment.

New Inventions.

A CUP-AND-BALL ANEURYSM NEEDLE FOR DEEP LIGATIONS.

While investigating a means of tying, from behind, the first part of the left subclavian artery, I asked the students in the dissecting-room of the Royal College of Surgeons, Ireland, to test the description and simplicity of my method. Using ordinary aneurysm needles they tied the vessel correctly, but it was plain that a better tool would have made the task yet more simple. When the needle was threaded and then passed, the ligature lay back along the shaft and was difficult to catch in the deep wound ; while if the needle were passed unthreaded it was not easy to expose and thread the terminal eye.

On experiment I found that an ordinary hooked dental stopping implement passed easily under the artery, and it occurred to me that if the smooth ball-tip of the instrument were detached and pierced like a bead, and if the stem were hollow with a mouth wide enough to seat the ball, the ball could then be strung on a thread passed through the stem. The thread being pulled taut, the ball would be firmly fixed to the cupped end of the stem and the implement could be passed like an ordinary aneurysm needle under the vessel. It would then remain merely to pick up the ball beyond the artery and thus retrieve the thread, which could be done under the guidance of vision or of touch by means of a fine hairpin bent into a sort of elliptical loop. Keeping the thread taut, the ball was first made to enter the wide part of the loop and was then caught at the constriction. The thread was relaxed and the ball withdrawn.

I have had another and smaller model of this needle made for ligating the middle meningeal artery as a preliminary to operation on the root of the Gasserian ganglion or the cavernous sinus. With modern technique the aperture in the temporal fossa has a diameter of about 3 cm., and the artery leaves the foramen spinosum some 5 cm. from the surface of the zygoma. Thus here, too, a deep vessel is tied through a small unyielding gap. Mr. A. A. McConnell and I have found that with my instrument ligation of the artery at the foramen spinosum becomes extremely simple.

These cup-and-ball needles have been made for me by Mr. Edwin Haines, of Dublin.

Arnold K. Henry, M.B. Dub., F.R.C.S. Irel.

THE LANCET.

LONDON: SATURDAY, APRIL 5, 1924.

EMMETT HOLT AND HIS WORK.

In his Goulstonian lectures for 1924 on Some Wasting Disorders of Early Infancy, the first of which is published in our present issue, Dr. Leonard Parsons repeatedly refers to the writings of the late Dr. L. Emmett Holt on the same subject. This is a timely reminder that the death of this eminent physician in Peking in January last, was, at the time, allowed to pass with scant mention either in American or English medical journals, an omission which only the exigencies of distance and the absence of detailed information can excuse or explain. The journey to the East which resulted in the greatly regretted loss of Dr. Holt was undertaken in connexion with an arrangement made with the Union Medical College of Peking to give a series of lectures on the subject of pædiatrics to the students of this older civilisation.

Dr. Emmett Holt, whose place in medicine it will be most difficult to fill, represented a type of physician with which we were until recently quite unfamiliar in this country. He was solely and exclusively what is known in America as a pædiatrist; that is to say, he practised as a specialist in the diseases of children and dealt with no other kind of case. In this respect he differed from his contemporaries in this country who, almost without exception, practise in general medicine as well. He differed also from the German professor of pædiatrics in that he had no research laboratory, and, at any rate, until recently no following of students eager to work for their chief and share with him the crumbs of honour falling from the great man's table. Dr. Holt was pre-eminently a clinical physician with great clarity of vision and a real flair for teaching. His famous text-book on the Diseases of Infancy and Childhood, which has been translated into no fewer than four foreign languages and which has passed through many English editions, has been the sheet-anchor of thousands of medical practitioners in every part of the world. No book has done more to make accessible to the whole profession the many brilliant discoveries which of recent years have illuminated the entire field of pædiatrics. There can be little doubt that the appreciation in which Dr. Holt's writings are held is well justified, for he was a past master of accuracy and clearness of expression. Although he has frequently been described as a great scientist, it is improbable that his eventual claim to fame will rest on this reputation. His practice and teaching were, it is true, based on a sound pathological and physiological groundwork, but he was neither pathologist, physiologist, physicist, nor biochemist; he knew just enough of all these sciences to make him, in view of his enormous clinical experience, a sound practical physician and a first-rate teacher. He discovered no new disease, neither did he lend his name to any new symptom or complex of symptoms, but all the same it has probably been given to few men to make so many comparatively little known diseases among children, comprehensible to others and amenable to treatment. Dr. Holt was 69 years of age when death overtook him in Peking, and it speaks eloquently for the elasticity of his arteries and the adaptability of his mind that during his later years the character of his work became modified and modernised in conformity with the changed conditions of medicine. As one of the original members of the board of directors, and as secretary of the Rockefeller Institute, he began before it was too late to appreciate and participate in research and experimental work of various kinds calculated to throw light on the problems of nutrition, and he collected around him a few of the younger generation of scientists who are able and content to devote their time to research for its own sake. To anyone who compares one of the last of Dr. Holt's publications—namely, a little volume [1] entitled Food, Health, and Growth—with any of his earlier writing this change of attitude, and leaning to the more scientific method, will be abundantly apparent. At the time of Dr. Holt's death he was physician in charge of the Babies' Hospital in New York, to which he devoted most of his time. Previously he held the posts of professor of diseases of children in the New York Polyclinic Medical School and Hospital. During the years 1901 to 1920 he held the post of clinical professor of diseases of children at the College of Physicians and Surgeons.

Although Dr. Holt's personal inclinations were always in the direction of preventive medicine, he played no great part in the world-wide campaign to promote the welfare movement, until the time when two American Associations, the Child Health Organisation and the American Child Hygiene Association, were consolidated and merged in the one society, the American Child Health Association, of which he soon became the moving spirit and inspired leader. It was largely in connexion with the missionary work of this Association that he took his fatal journey to Peking, a journey intended to bring to the youth of an ancient civilisation the inspiring message of American welfare work.

◆

CANCER AND CIVILISATION.

The incidence of cancer in the different races of mankind has always presented an interesting aspect of the cancer problem. Medical men working among uncivilised races have returned to Europe with the tale that they had seen very few cases of cancer among those peoples. The impression was thus created that cancer was a disease of civilisation. In a sense that must necessarily be true. For cancer becomes increasingly more frequent as age advances, and affects particularly those of middle age, between 45 and 60. Uncivilised races know nothing of time, and cannot give an account of the length of their individual lives. But it is safe to say that civilisation has greatly prolonged our average span of life, and that therefore the number of people likely to be affected by cancer is much smaller in uncivilised races than in civilised races. Morover, civilisation inculcates a respect for age which seems absent from the mind of the tribes that kill their old people when they can no longer take part in the hunting and fighting, and have become a burden to the community. Civilisation tends to work in the opposite direction, and even to sacrifice the young to the old in certain directions. It thus alters the age-constitution of the population in such a way that the absolute number of cases of cancer must necessarily be greater than in an uncivilised population, even if no other factors were operative. If we consider further that in uncivilised regions large areas are sparsely populated, it is easy to see how a medical man working in such a region and trained in a hospital in one of our densely populated towns, may form the impression that cancer is of rare occurrence among uncivilised races.

---

[1] The Lane lectures (reprinted) given at the Medical School of the Leland Stanford Junior University in San Francisco.

This alleged freedom from cancer of uncivilised races has been the subject of repeated investigations during the last 20 years. The first comprehensive inquiry was carried out in this country by the Imperial Cancer Research Fund. Cancer was found wherever it was looked for by competent observers, and the fact was established that cancer is a disease common to mankind throughout the world. In so far as African races are concerned von Hansemann came to a similar conclusion a few years later on the basis of material collected from the German colonies. Some interesting results were obtained from those studies concerning the organ-incidence of cancer in different races—results which clearly pointed to chronic irritation as being the determining factor, as exemplified by betel-nut and kangri cancer. But it was also recognised that there was no statistical basis for a comparison of the frequency with which cancer affects uncivilised and civilised races. As we go from the equator to the poles the same story repeats itself. The tale is put about that among Eskimos in Greenland cancer is unknown; the Danish Government appoints a commission to investigate the matter, and cases of cancer are found. Their number was necessarily small because the total population is small, but owing to the special conditions obtaining in Greenland it was possible to make an estimate of the size of the population, and obtain an approximate analysis of its age-constitution. Prof. J. Fibiger, who reported on the results of this commission, was thus led to the conclusion that cancer affects the Eskimos with approximately the same frequency as the Europeans.

The paper by Mr. R. V. Dolbey and Mr. A. Mooro on the Incidence of Cancer in Egypt, which we published on March 22nd, is a further and useful contribution to the subject of the organ-incidence of cancer in the native races of Egypt. These authors state that cancer is less frequent in Egypt than in England, but we can draw no such deduction from the data which they supply, for the number of cancer cases in a hospital does not reflect the incidence of the disease in the whole population, and comparison is hardly admissible between the number of cancer cases in a hospital in Egypt and in England. Even if it were a reflection, it would be of little statistical value, so long as we do not know the size of the population of which the hospital population in Egypt is supposed to be a reflection nor its age-constitution. Of considerable interest, however, is the consideration of the organ-incidence. Perhaps the most striking fact is the relative rarity of intestinal cancer, which the authors attribute partly to the diet. The idea that diet is related to the incidence of cancer of the stomach and intestine has much to commend itself. It is interesting to note that the diet followed by the fellaheen is characterised by an abundance of vitamins, which, as the recent work of McCarrison and of Cramer has shown, are specially concerned in maintaining the functional and structural integrity of the alimentary canal. The further suggestion that the presence of digestive troubles, generally resulting from the mental stress and strain of civilised life, are a condition predisposing to cancer of the alimentary canal is also a reasonable one. On the other hand, if these two factors are really of such ætiological importance as the authors suggest, we might expect to find some clinical correlation from the data in civilised countries between the incidence of intestinal cancer and certain professions, or at least certain physical and mental types of patients. No such clinical evidence appears to exist. The difficulty of correct diagnosis is so great that many cases of intestinal cancer are treated for such a condition as anæmia, and their true nature is first recognised at the post-mortem examination. It would be interesting to know the number of autopsies carried out at Kasr-el-Ainy, for, broadly speaking, the number of cases of cancer recorded by a hospital is in proportion to the frequency with which such examinations are made.

We may have to debit civilisation with creating conditions predisposing to intestinal cancer. But if we do so we must also credit it with diminishing the incidence of other forms of cancer, such as rodent ulcer, cancer of the scalp, or cancer of the bladder. Civilisation may therefore shift the organ-incidence of cancer. It may increase the incidence in one organ and diminish it in another. It cannot be incriminated wholesale as a cause of cancer generally. In fact, it would not be paradoxical to say that the *recorded* incidence of cancer in a community is a measure of its degree of civilisation. The prolongation of life, the ordered communal life which renders trustworthy vital statistics possible, an efficient medical service that ensures accurate diagnosis of a disease which has no characteristic symptomatology, and an intelligent population that takes advantage of such a service:—all these are factors of civilisation which tend to raise the actual as well as the recorded number of cancer cases in a community.

THE DOGS' PROTECTION BILL.

For the modest sum of 6*d*. net there can be obtained from His Majesty's Stationery Office No. 21, Vol. LVI., Parliamentary Debates, House of Lords, in which will be found the proceedings which attended the Second Reading of the Dogs' Protection Bill in the Upper House last week. The Second Reading was proposed by Lord Banbury, who has already stood sponsor for the measure on previous occasions in the House of Commons, and the debate which followed his Lordship's introduction was a model of the way in which a far-reaching subject, touching at one end our commonest instincts and at the other our highest scientific equipment, should be conducted. The speakers were eloquent, and on both sides it may be freely conceded that the purpose of their words was elevating and humane. Lord Banbury in his plea for the Bill had, of course, to rely upon the age-long friendship between the man and the dog for his arguments against the employment of dogs in physiological experiments. His words were frankly addressed to the heart, and were reinforced by apt and moving citations from the written and spoken words of others. Indeed, for his purpose, it would be well if his Lordship attempted to employ no other arguments than those supplied from literature or drawn from the common knowledge that we all accept the dog as a friend, for when he brings up his scientific battalions their fighting quality is unimpressive.

Once again we must protest against the implied use of The Lancet as among Lord Banbury's scientific supporters of the Dogs' Protection Bill. Though we claim as high a degree of affection and respect for the dog as his Lordship himself, we are out of place in that category, while the appearance of The Lancet as, though involuntarily, being one of his backers, can only be due to a suppression of facts. In The Lancet of May 31st, 1919, we published a memorandum issued by the Medical Research Committee upon the Dogs' Protection Bill, and in an editorial note upon this

Memorandum the following two consecutive sentences occurred :—

> "The Memorandum of the Medical Research Committee which we also print in substance this week demonstrates, without reasonable pretext for gainsaying, that the experimental use of dogs has advanced our knowledge and has been of benefit to suffering humanity. This is not to say that such knowledge could have been acquired in no other way."

The meaning of the extract quoted was and is perfectly clear to a medical audience, and it is simply not the fact to suggest, as Lord BANBURY has done, that, perhaps without knowing what we were doing, we have supported his measure. The impression produced by a verbatim quotation of the second sentence, while omitting the first or only alluding in some general way to its content, is a grave misrepresentation.

We need not recapitulate in these columns the undoubted benefits both to the man and to the dog which have accrued from scientific experiments upon canine subjects. The story of the researches into diabetes and rickets, for example, are familiar to all our readers and no better summary of their results can be found than in the official report to which we have referred above. Such information is there resumed with clearness and accuracy by Lord KNUTSFORD and Lord RAYLEIGH. We know of no other way as yet in which such valuable knowledge could have been acquired save by using the dog as the test object. But this is not to say that in time to come some future scientific developments may not enable analogous researches to be undertaken upon lowlier animals, nor, indeed, that the use of any animal as a test object may not be superseded in some experiments where it must now be employed.

◆

ADVERTISING HEALTH.

THE Glasgow Public Health Department have made a new departure by issuing a monthly health bulletin. We have received copies of the first two issues. Each consists of four pages. The first page deals shortly with diseases which have been prevalent or to which attention has been drawn during the month. The second page deals with birth- and death-rates during each of the four weeks. The infant mortality-rate might be added to this statement with advantage. The third page gives the notifications of disease and meteorological records week by week, and the fourth page the addresses and hours of the various infant welfare centres and tuberculosis dispensaries. The first issues are being sent to the consulates, public libraries, and medical practitioners, and also to anyone who writes expressing a desire to be supplied with them. These issues are couched in technical language, and seem intended chiefly for medical practitioners and others who have made a special study of public health matters, but there seems to be no reason why a health bulletin of this kind should not be made much more attractive with a view to arousing the interest of a wider circle; in fact, of every intelligent citizen. We all recognise that the public health depends mainly upon the effort of each individual to lead a healthy life, and such a bulletin might make a much more direct appeal to the individual. For example, each bulletin might be associated with a motto or a tilt against some prevailing habit inimical to communal health. Both the United States and Canada have developed this idea of advertising health much more than we have, and we might well take a leaf out of their books. We think there are great possibilities in front of the health bulletin; it should, however, be not only a more or less dismal record of the prevalence of disease, but also an inspiration towards more abounding health.

Annotations.

"Ne quid nimis."

THE PANCREAS IN RELATION TO DIABETES MELLITUS.

THE starting-point of our knowledge in the ætiology of diabetes mellitus is usually stated to be the discovery by Mering and Minkowski in 1899 that extirpation of the pancreas led to the disease. Although this observation was the first experimental proof of the association between the pancreas and diabetes, the idea was much older. Thus, Conrad Brunner, over a hundred years before these investigators, attempted to prove that the pancreas was concerned with glycosuria, and early in the nineteenth century Richard Bright prepared a specimen for the Guy's Hospital Museum "to show the relationship between the pancreas and diabetes." The specimen consisted of a fibrosed pancreas. Another point sometimes overlooked is that neither Mering nor Minkowski associated the islets of Langerhans with diabetes, but attributed the anti-diabetic functions to the whole organ. The truth of this statement is borne out by the appearance of a large number of papers at that date giving the clinical results of treatment by oral administration of the whole gland. It was not until several years later that Opie and others called attention to the possibility of locating the anti-diabetic function in the islets described by Langerhans in 1860. This view was supported by the contemporary work of Laguesse, who proved that the degeneration caused by ligation of the duct did not affect the islets, and later by the work of Rennie and Fraser on the islets of teleostean fishes. The Toronto workers have also supported the classical views, since they state that, in fish pancreas, insulin is found almost exclusively in the main islet. As the result of histological and experimental evidence, it has become an accepted fact that the anti-diabetic hormone is secreted by the islets, and that diabetes mellitus is due to some demonstrable lesion or functional derangements of these organs.

It must not be supposed, however, that the independence of the acini and islets has been unchallenged. Many workers have been opposed to this doctrine, and in our present issue an article by Prof. Horst Oertel appears, in which the case against the islets is marshalled. The evidence in favour of the independence of the islets is stated, and is criticised point by point. The work of Milne and Peters is quoted fully, in which it was shown that definite connexions between the islets and acini could be demonstrated by serial sections. Furthermore, in the histological examination of sections showing pancreatic degeneration due to any cause, it is possible to see acini taking on the appearance of islets, and islets disappearing. Special staining reactions give no definite demonstration, and hence do not afford support to the classical views. Prof. Oertel has, indeed, set out a strong case to show that the islets are really part of the general parenchyma; at any rate, the evidence upon which the orthodox view rests is quite flimsy. The author stresses the idea that diabetes is due to excessive breaking down of glycogen, and that insulin acts by inhibiting this. It has been shown by most workers, however, that glycogen disappears from the liver in insulin convulsions, and the greater part of the experimental evidence on the pharmacological action of insulin does not support such a theory. We have, however, no definite proof that insulin is a secretion from the islets of Langerhans. Collip has obtained insulin in small quantities from many animal tissues, and bodies very similar to insulin from plant sources. Prof. Oertel's suggestion that the insulin action is a general cell function, and the fact that active material can be prepared from any animal organ, both raise speculations as to whether the pancreas possesses the monopoly for making this substance. There is no conclusive evidence that the pancreas alone can form insulin.

The whole question of the pathology of diabetes and of the pharmacological action of insulin is in the melting pot, and perhaps it is as well that the foundations of the classical views are being thoroughly exposed for inspection.

AN INVESTIGATION INTO BRONCHO-MONILIASIS.

A LABORIOUS investigation recorded in the *Medical Journal of South Africa* (Vol. XIX., p. 101, November, 1923) by Dr. A. Pijper suggests that bronchomoniliasis is neither a clinical nor a pathological entity. The Unna-Pappenheim method for staining the Ducrey bacillus was found to be a useful differential stain for monilia fungi, and its value was confirmed by the results of applying a special culture method, using an acid medium (pH2). In the course of 67 consecutive examinations of sputum, mostly undertaken to try to confirm a clinical diagnosis of pulmonary tuberculosis, Dr. Pijper was able to demonstrate by these methods the presence of monilia fungi in 36 cases. Having endeavoured unsuccessfully to grow monilia fungus on suitable media exposed to the air of the laboratory, though a large number of other fungi were grown in this way, he concludes that this fungus is not omnipresent, and that its incidence in sputum collected with the usual precautions may safely be ascribed to the patient. The severity of the symptoms occurring in the patient examined could not be correlated with the number of fungi found in the sputums, which varied considerably. Forty-three different species were differentiated by biochemical methods, and an attempt was made to estimate the pathogenicity of various strains by inoculation into the trachea of rabbits. No relation could be established between pathogenicity and cultural, biochemical, or morphological characteristics. In some rabbits lesions were produced by strains derived from milk or from human sputum where monilia was present in small numbers; whereas monilia which appeared in large numbers in human sputa sometimes had no effect on a rabbit. Dr. Pijper concludes that we possess no means of distinguishing between saprophytic and pathogenic monilias, and that it is doubtful whether the pathogenicity can be held to be dependent on the number of monilià elements present. He describes certain morphological characteristics of a constant nature on which, he suggests, a division of the monilia group might with advantage be founded.

X RAY DISEASE OF THE LARYNX.

X RAY disease of the larynx is an illustration of the common phenomenon that the rare disease discovered yesterday is the common disease of to-day. Four years ago severe X ray disease of the larynx was practically unknown, yet in the interval more than a dozen cases have been reported, and doubtless many others have been recognised but not published. A paper by Prof. Ove Strandberg in *Ugeskrift for Laeger* for Feb. 28th summarises the already bulky literature of this new subject and deals with the difficulties of the differential diagnosis as illustrated by a case sent to the Finsen Institute in Copenhagen with the diagnosis of tuberculosis of the larynx. The patient was a man aged 41, who, two years earlier, was operated on for a gland in the neck. As the operation wound broke down 14 days later, he was given X ray treatment in February and March and again in June of the same year (1922). In April, 1923, the destructive changes found in his larynx were diagnosed as tuberculous, but a careful examination in the Finsen Institute gave no support to this diagnosis, nor to that of syphilis or malignant disease. Exploratory excision and microscopic examination left no doubt that the ulceration and necrosis of cartilage were the outcome of the X ray treatment (the dosage of which is not stated), although there had evidently been an interval of several months between the last exposure and the development of the characteristic X ray changes. Prof. Strandberg classifies the X ray reactions of the larynx in three groups. The first includes the numerous and long-known cases characterised by hoarseness and œdema occurring from one to three days after an exposure, and lasting only for as many days. This reaction is generally regarded as harmless, and it has not been known to necessitate tracheotomy on account of œdema of the larynx. The second group includes those reactions which occur 10 to 20 days after an exposure, the patient suffering from a laryngitis sicca and, in some instances, from hoarseness and œdema of the larynx. Though this condition may be serious, it usually subsides in 10 to 14 days, but even though only a single exposure has been given, the œdema may necessitate tracheotomy. While the reactions in the first two groups are comparatively harmless, the reaction in the third group is often rapidly fatal. How long after a single exposure or a series of exposures this reaction may begin is not yet known; the longest interval hitherto recorded would seem to be 12 months (van Rossem's case [1]) and the shortest interval four weeks. Whereas in the first two groups the reaction occurs chiefly in the skin and subcutaneous and submucous tissues, the reaction in the third group involves muscles, cartilage, and glands which undergo necrotic changes. Tracheotomy and other operations in such cases are apt to be disastrous, as X ray ulcers may develop in the operation wounds, and for the same reason laryngectomy is contra-indicated. With regard to the dosage of the X rays, it is disconcerting to find that in none of the 13 cases collected by Jüngling was the dosage in excess of that commonly regarded as within the limits of safety. This disease may apparently develop in any case if the X rays traverse the region of the larynx, whether they be given for glands in the neck, sycosis, cancer, or any other disease. As for cancer of the larynx, Jüngling attaches so much importance to the risk of X ray disease as a sequel to X ray treatment that he insists on never giving it for a cancer of the larynx which is operable. Before more is known of the conditions under which X ray disease of the larynx arises, many of us will assuredly experience a certain dilatory inhibition when X ray treatment is recommended for morbid changes which occur in the neighbourhood of the larynx and which are amenable to less risky treatment.

LATE SERUM SICKNESS.

Dr. T. T. Crooks,[2] of the Durand Hospital of the John McCormick Institute for Infectious Diseases, reports the case of a woman, aged 26, who developed acute pharyngitis with œdema of the uvula. She had had two courses of toxin-antitoxin and was negative to the Schick test, but as she had been intimately associated with cases of diphtheria she was injected intramuscularly with 20,000 units of diphtheria antitoxin. Cultures from the nose and throat showed no diphtheria bacilli, but numerous hæmolysing streptococci. Four days after the injection urticaria appeared at the site of injection and in another three days became generalised, when the patient suffered from continuous nausea and vomiting and became cyanosed and pulseless. Atropine and epinephrin were given hypodermically, and the patient rallied, but was tormented for five days by the urticaria, which was only relieved by injections of epinephrin. From the second day of the urticaria she had very severe muscular and joint pains. The temperature ranged from 99·2° to 103° F. The blood showed a leucocytosis of 18,100 at the onset of the urticaria with 72 per cent. of polymorphonuclears, 25 per cent. large lymphocytes, 2 per cent. small lymphocytes, and 1 per cent. eosinophils. The remarkable feature of this case was that a reaction of such severity did not become severe until seven days after injection. It is possible that the antitoxin in the toxin-antitoxin mixture given two years previously had sensitised the patient, though no previous example of such sensitisation has been recorded.

CARBON TETRACHLORIDE AS A REMEDY AGAINST INTESTINAL PARASITES.

IT is difficult in England to realise the importance which intestinal parasites play in tropical medicine. The difficulty of treating these parasites by vermifuges is considerable, and it is not surprising that new remedies are constantly making their appearance. The introduction in America of carbon tetrachloride for the treatment of ankylostomiasis,[1] and the extremely successful results reported from its use by mouth in doses not exceeding 3 c.cm. for an adult, is interesting in view of the well-known toxicity of this drug. In 1909 a death occurred whilst it was being used for "dry shampoo" purposes in a hairdressing establishment, and as a result of the publicity given to the matter by the coroner's inquest it is probable that it has been almost entirely abandoned for this purpose. In 1914 Sir William Willcox recorded a case of death due to this substance occurring in a man using it whilst working in an aeroplane factory, and in 1915 the same observer described in our columns[2] a number of cases in aeroplane workers. Toxic jaundice was the characteristic symptom, and post-mortem examination showed diminution of the size of the liver, marked degenerative changes of liver, kidney, and heart, and the deposition of fat in these organs. If the patients lingered some time before death there was much less fat, but there was marked destruction of liver cells, their place being taken by newly formed fibrous tissue, "replacement fibrosis." Trinitrotoluol, dinitrobenzene, arseniuretted hydrogen, phosphoretted hydrogen, arsenobenzol derivatives, and many other compounds may cause similar results. Recently, in view of this use of carbon tetrachloride, Meyer and Pessoa have carried out a number of experiments on dogs, by the administration of this substance to them in varying amounts, with a view to ascertaining the toxicity and suitable dosage of the drug, and, in the majority of experiments, obtained lesions similar to those described by Willcox. They conclude: (1) That carbon tetrachloride has a toxic action on dogs when administered orally; (2) that the presence and extent of the lesions vary in proportion to the amount of the drug given; (3) that with the same dose the lesions are more severe the older the animal (a point to be borne in mind when large-scale sanitary campaigns are being planned—i.e., when it is proposed to treat the whole population of any given area); (4) that the administration of an oil or saline purge with the drug tends to diminish its toxic action; (5) that the doses recommended by M. C. Hall (who introduced the remedy) are probably too large, since, when treating a group of cases by Hall's method, three cases of lumbar pain occurred (one with hæmaturia), and other symptoms occurred in other patients; and (6), that carbon tetrachloride is indeed a powerful vermifuge to ankylostomiasis. P. D. Lamson and others, writing in 1923, have also studied the oral and intravenous administration, and by the latter method found that 0·154 c.cm. of the drug per kg. of body-weight was lethal. They also found that the pathology consisted essentially of damage to the liver, one of the first manifestations of which was the appearance of abnormal amounts of bilirubin in the blood. They used carefully purified carbon tetrachloride. L. E. Warren in 1923, having regard to this treatment, discusses the purity of carbon tetrachloride and points out that, as this drug is usually manufactured by chlorinating carbon disulphide, the likely impurities are chlorine and carbon disulphide. The former is rare, but the latter common. Nine samples of the drug were examined; one was free from carbon disulphide, and the remaining eight contained amounts varying from 0·015 to 0·27 per cent. of carbon disulphide. Although there is no doubt that carbon tetrachloride is responsible for the lesions described, it seems important that pure samples of the drug should be used. From the above considerations it seems doubtful whether carbon tetrachloride given in amounts sufficient to act as an efficient vermifuge is a safe drug to employ.

MASS METHODS IN MEDICINE.

WITH the growth of knowledge of the morbid physiological processes which constitute disease, and the elaboration of methods for investigating and assessing them, the art of diagnosis has reached a complexity undreamed even 30 years ago. There can be no hope of return to the days when a cultivated power of observation sufficed to the diagnostician; though, on the other hand, the day will certainly never come when the physician will be able to dispense with that same power of observation in favour of some trick done with a test-tube or burette. As knowledge progresses, however, it is probable that matters will become somewhat more simple; already this process is showing its results in treatment, and to some extent the complexity of present-day diagnostic methods as compared with those of former times is offset by the simplification in recent years of modern therapeusis. With the multiplication of special departments for diagnosis and treatment, the problem of their correlation so as to secure results in the most efficient and economical manner becomes pressing. For the guidance of the specialists there exist whole libraries of manuals, mostly excellent. For those responsible for the correlation of the various departments, however, works of guidance have, up to the present, been lacking, and proportionate welcome will be afforded to an attempt by Dr. George R. Herrman[1] to supply a concise but comprehensive statement of the arrangements for diagnosis and treatment of patients in the service of Dr. George Dock at the Robert Abbott Barnes Hospital, St. Louis. The book had its origin in a series of typewritten sheets of rules and suggestions supplied to the house staff by Dr. Dock when he was attached to the medical school of Washington University. By accretion these grew into the manual which in its present state affords a complete system of hospital management from the standpoint of the chief physician and his assistants.

One of the points of particular interest in this work is the light which it throws upon the way in which problems common to all great hospitals are dealt with in one particular instance. The American system of arranging the work of the house staff is described in Part I., which is devoted to administrative methods and contains rules for the guidance of all members of the medical staff from the resident physician to the clinical clerks. It is interesting to note that search is almost vain for rules for the conduct of the medical student; apparently he is not so important a person in the American as in an English medical school. Almost the only reference to his duties in Dr. Herrman's book occurs on p. 31, where he is instructed to step promptly to the bedside and give the patient's name. Most of the other things which in an English hospital are, or ought to be, done for the patient by the student seem in America to be done by the "interne." There may be some doubt as to which system is the better for the patient; there can be none as to which is better for the student. Suggestions as to case-taking and a description of the simpler routine methods of laboratory investigation are also included in this section. In Part II. are described the special laboratory methods of investigation of cases of all types in general use in the hospital. Together with the last part of the preceding section this constitutes a complete manual of clinical pathology, the peculiar value of which is that it has been compiled by physicians as the result of their experience of the utility of the methods described. Parts III. and IV. are devoted to dietetics and therapeutics. As to the latter, it is significant that it is the shortest section in the book. The number of drugs recommended for use is strictly limited, and it is urged that they be prescribed separately. One of the less fortunate effects of specialisation is evident in the chapter on hydrotherapy which includes the Scottish douche, the whirlpool bath, and other tempests in teapots, but in which the sponge and blanket bath escape all mention. In the section on dietetics are given extensive tables of the caloric equivalents of most of the foods in ordinary use in this country and America. Diets are given for almost every type of case from diabetes to constipation. In bringing together in a remarkably concise manner a large amount of information now dispersed in various manuals and journals, this section is of particular value. In the last part the actual forms and graphic methods used in recording all the facts concerning a patient are illustrated; as they number 74 it may be assumed that the Barnes Hospital will from time to time require new buildings to house its records.

[1] Methods in Medicine. The Manual of the Medical Service of George Dock, M.D., Sc.D., formerly Professor of Medicine, Washington University School of Medicine. By George R. Herrman, M.D., Ph.D., Instructor in Medicine, University of Michigan. London: Henry Kimpton. 1924. Pp. 521. 30s.

This book may be said to be unique in the sense that nothing of the sort has been published before. That there was need for such a manual there can be no doubt, and this volume should prove of the greatest value to all responsible for the conduct of institutions, be they public or private, for the care of the sick.

LUES AND "LUETISM."

We have received from Prof. Eugene Hertoghe, of Antwerp, and Prof. William Seaman Bainbridge, of New York, a joint communication entitled "Lues and Luetism," in which the writers wish to stress the following points:—

1. Non-malignant duodenal and gastric ulcers are more often of a syphilitic origin than is generally recognised.
2. Duodenal and gastric ulcers have frequently healed under the administration of bismuth which has recently been proved of anti-luetic value.
3. These ulcers may be due to an underlying factor non-reactive to any test, which the authors term "luetism."
4. Necessity for standardisation of the Wassermann technique, it being recognised that a positive Wassermann is merely a link in the chain of evidence of syphilis. "Moreover a possible form of lues which may have been modified by passing through many generations—'luetism'—might prove peculiarly non-reactive to the Wassermann or any other known test for syphilis."
5. Because iodine has been helpful in abnormal thyroid, the cause of this abnormality may be in many cases "luetism," the improvement in the physical and mental state under iodine being often due to the anti-luetic action of the drug.
6. "Luetism" may cause gastro-intestinal disease, accompanied by psychopathic states, and its recognition may be the explanation of these conditions. Syphilis causes much trouble in the blood-vessels and frequent mental disorders.
7. Finally, no one cause will explain all disease, and the underlying factors in each case must be thoroughly investigated.

It will be seen that these points are put in very guarded language, and there is nothing in the paper to show, for instance, how often duodenal and gastric ulcers are of syphilitic origin. Bismuth certainly has been found of value in these ulcers, but it is arguing in a circle to assume that because bismuth is also useful as an anti-syphilitic remedy, therefore these ulcers are of syphilitic origin. The same method of reasoning is applied to iodine and abnormal thyroid function.

The authors wish to add to medicine, already overburdened with vague conceptions, a new complex "luetism," non-reactive to any known tests, but an underlying factor in many conditions—a syphilis, in other words, that is not syphilis. "The basic purpose of this paper is to stimulate interest in certain very promising fields of medical research, and perhaps to contribute something towards the final solution of this multiplex problem of *syphilis*." We agree that to stimulate interest in any field of medical research is a worthy object, but we must express a doubt whether this is best achieved by the making of hypotheses incapable of being put to proof.

MATERNAL MORTALITY.

The third of a series of reports[1] by Dr. Janet Campbell, a senior medical officer of the Ministry of Health, on the problem of maternal mortality has just been issued. Mr. Wheatley, the Minister of Health, who contributes a prefatory note, reminds us that Miss Campbell's two previous reports dealt respectively with the education of the medical student and the training of the midwife in the science and art of obstetrics. The present memorandum is concerned with the cause of excessive maternal mortality and the means for its reduction, the subject being reviewed from the public health rather than from the clinical aspect. Briefly, the evidence furnished in this exhaustive inquiry shows that the mortality-rate of women from childbirth is unnecessarily high in England and Wales, which is the area covered by Miss Campbell's investigation. The problem of excessive maternal mortality and morbidity is common to all parts of the country, although, generally speaking, the mortality tends to be highest in sparsely populated rural counties and in industrial districts, notably those associated with the textile industries of Lancashire and Yorkshire and with coal mining, and tends to be lowest in the south of England, in London and the districts around it, and in certain large towns such as Birmingham, Liverpool, and Manchester. Apart from the disturbing mortality figure, approaching 4 per 1000 births, it would appear certain that large numbers of women are injured at the time of childbirth and that this injury, however slight it may appear at the time, leads to much suffering and economic distress, none the less real because in many families it may not be ever traced to its actual source.

The difficulty of assessing the general causes which influence maternal mortality is admitted by Miss Campbell, but she has satisfied herself that the adequacy or otherwise of the professional attention given during pregnancy and at the time of birth is a weighty factor. In a large number of maternal deaths there has been at some point a failure in proper supervision. Often the omission occurs before childbirth; there has been a lack of antenatal watchfulness, and what might have been a comparatively simple event becomes one of desperate urgency. Familiar instances are the failure to handle a difficult case with due skill and judgment; failure to take satisfactory antiseptic precautions, especially when operative measures are concerned; failure subsequently to examine the patient with sufficient thoroughness and so to ensure the repair of injury. Omissions such as these may readily lead to a fatal termination. In other instances an adverse result may be almost unavoidable. For example, in an isolated district it may not be possible to obtain medical help in time; expert medical advice or hospital accommodation may not be available for a complicated case, while the patient herself may be to blame for neglecting to take reasonable precautions. Curiously enough, insanitary conditions appear to have less direct influence upon puerperal mortality than might be supposed; nor has employment of married women had direct influence upon the maternal death-rate, at any rate as far as the nature of the occupation is concerned, though the double strain of housework and outside employment may impose too heavy a burden upon the mother with diminution of her powers of resistance.

Miss Campbell's suggestions for securing reduction in puerperal mortality and morbidity are set out under three main headings: (1) Improvement in the quality of professional attendance; (2) action through the public health department of the local authority; (3) social and educational measures. Under the first heading she urges adequate education of the medical student and better training of midwives; also the employment of the trained midwife for maternity nursing with the consequent disappearance of "nursing" by the unqualified handy-woman. Closer coöperation between practitioner and midwife, between professional attendants and local authority are greatly to be desired. The public health department of the local authority can assist preventive midwifery by organising ante- and post-natal care of pregnant women at maternity centres. More maternity beds are needed for observation, isolation, and treatment of complicated cases, and for the accommodation of women who cannot safely and suitably be confined at home. A sufficient service of competent midwives should be assured to women confined in their homes, if necessary by subsidy of the midwives practising in sparsely populated districts or by assisting the formation of district nursing associations. The attendance of a midwife, the assistance of a trained nurse, and the advice and treatment of a medical practitioner should be available for all necessitous patients requiring such services. Maternal deaths due to childbirth should be investigated by the medical officer of health, also all cases of puerperal infection, whether fatal or not. Amendments may be desirable in the existing provision for the notification of puerperal fever. Social and educational measures include the provision of suitable nourishment for necessitous expectant and nursing mothers, extension or modification of sickness benefit during pregnancy, and widespread propaganda.

---

[1] Reports on Public Health and Medical Subjects. No. 25. Maternal Mortality. By Janet M. Campbell, M.D., M.S. Ministry of Health. London: H.M. Stationery Office. 1924. Pp. 112. 1s.

The inquiry is not yet complete. Miss Campbell proposes to report later on the clinical aspect of mortality in childbirth. The matter deserves attention, for whereas infantile mortality has diminished by one-half during the last 20 years, maternal mortality has remained almost stationary. And the reproach is not limited to this country, but applies equally to all the English-speaking countries. If the figures can be trusted, Scandinavia provides an example to emulate.

THE PART-TIME M.O.H.

MANY of us have viewed the supersession of the part-time medical officer of health with regret, but for some time it has been evident that in communities of a certain size a whole-time administrator for public health purposes has been necessary. The borough of Enfield, we learn from the *Enfield Gazette and Observer*, is divided in its opinion as to the advisability of agreeing with the view of the Ministry of Health and appointing a whole-time medical officer; and we observe that our contemporary is advocating that one of the largest parishes in England should be satisfied with the services of a part-time medical officer on the ground of economy. The argument of economy can be carried too far. The Ministry of Health would be responsible for a large proportion of any whole-time salary; while, efficiently conducted as the sanitary business of Enfield appears to be, there may arise at any time situations with which no one but a whole-time and expert sanitarian can deal, when, if the results to the community were very expensive, the authorities would be held responsible. The part-time medical officer of health coöperates admirably with county authorities in rural neighbourhoods, but urban conditions impress upon communities the need for conformity with their similars, so that a well-staffed service may maintain the public health of the country.

A MEETING of the Fellows of the Royal Society of Medicine will take place at 1, Wimpole-street, London, W. 1, on Thursday, April 10th, at 5 P.M., with Sir William Hale-White, the President, in the chair, to meet the foreign medical officers of health now in this country, and to hear a lecture communicated by Dr. L. Rajchman, Director of the Health Section of the League of Nations, on the Health Organisation of the League. A preliminary address will be given by Mr. John Wheatley, the Minister of Health.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXV.

THE TREATMENT OF FUNCTIONAL DISORDERS OF THE HEART.

BY the term "functional disorder of the heart" is meant a condition in which the patient suffers from symptoms suggestive of heart disease, but in which his heart and arteries are healthy. The chief symptoms of which the patient complains are breathlessness, precordial pain, palpitation, giddiness, and exhaustion; these are caused or aggravated by exertion, and are accompanied by a quickening of the pulse greater than that found in health. Other features sometimes associated are: (1) signs of defective vaso-motor control, such as flushing of the skin, or, on the other hand, coldness of the extremities occasionally with local cyanosis. Attacks of syncope may occur as the result of transitory disturbance in the cerebral circulation; (2) symptoms of functional nervous disorder, such as nervous irritability or nervous exhaustion; headache and sleeplessness are common.

It must be emphasised that the symptoms described may form part of the clinical picture of many diseases; in the early stages of phthisis, for example, the circulatory symptoms may overshadow those directly due to the condition of the lung. It is obvious that before deciding that a patient is suffering purely from a functional disorder of the heart, the physician must exclude organic disease, not only in the heart, but in other situations as well.

Treatment may be considered under four headings: (1) reassurance; (2) rest and graduated exercise; (3) drugs; (4) removal of any cause likely to aggravate the symptoms.

Reassurance.

Anxiety about the state of the heart is present in varying degree in most patients, and it is essential to remove this. Reassurance must be given wholeheartedly, if the patient is to be convinced that he has not got heart disease; to say that there is no organic disease, but that the heart is "weak," "strained," or "flabby," does not carry the necessary conviction; the patient must be made to realise that his heart is absolutely healthy. Other methods of treatment are sure to prove unavailing until the patient's mind is set at rest, and in mild cases reassurance alone may be all that is necessary.

Rest and Graduated Exercise.

Rest in bed is definitely harmful to the large majority of patients; in a few of the most severe cases it is occasionally beneficial, but must not be prolonged.

Graduated exercise is an essential part of treatment in every case, but the best method of prescribing it varies. The patient should take the maximum amount of exercise of which he is capable without experiencing actual distress; if he oversteps this limit, his condition may undergo a slight but temporary deterioration, but no permanent damage, comparable to that which might result in a case of organic heart disease, follows. The tendency in most patients is rather to under-estimate the amount of exercise of which they are capable, and it is important to decide for each individual how far this is the case. This may be judged partly by a general estimate of the mentality, and partly by some such method as the following: the patient is told to step on and off a stool until he feels discomfort; the appearance of the patient when he stops, the character of his breathing, and his pulse rate show how far his distress is real. If he appears to be a man who does not complain unnecessarily, it is sufficient to tell him to take regular outdoor exercise, preferably of a kind that has some objective, such as golf or gardening, and gradually to do more as he finds that he can.

If, on the other hand, he complains of distress before any objective signs are apparent, he is probably a man who, if left to "train" himself, will not attempt an amount of exercise sufficient to ensure the maximum degree of improvement. In such a case, the best results will follow upon making him do a series of exercises every day under supervision. This can be obtained either by the physician seeing the patient at intervals or by a masseuse trained in giving graduated exercises: but in the latter case it is important that the physician himself should give instructions as to how much exercise the patient is to do, and how quickly the amount should be increased.

Universal rules for graduating the exercise cannot be set down, but the following will be found suitable for most patients. The scheme of exercises should last 15–30 minutes, and should include one exercise lasting 2–4 minutes, sufficiently severe to cause slight dyspnœa but not actual distress. This exercise will generally be found to be one which raises the pulse to a rate between 130 and 150 per minute;[1] two minutes after the exercise is over, the rate should not be more than 10 beats above the rate counted before exercise. (It may be urged that this rule places too much reliance on the pulse rate as the mark of the first sign of distress; possibly more attention should be paid to the facial expression and respiration, but it is much more difficult to appreciate the indications that these afford than to count the pulse; for this reason the pulse rate is in most cases a more satisfactory guide for the masseuse.) The hardest exercise should be done once or twice during each treatment; the other exercises should be easier. Stepping on and off a stool is a convenient form of the hardest exercise, for it is easy to increase it by a known amount; as the patient improves it is found that the stepping has to be done at a faster rate to get the desired effect on the pulse and respiration. A further advantage of grading the exercise in this way is that it affords a rough measure of the degree of improvement, obvious not only to the physician, but also to the patient; the latter is made to realise that he is becoming capable of a greater amount of exercise in a given time, and this has an excellent mental effect. Massage itself is of no value, and the so-called "Local Heart Treatment," which consists of different varieties of massage over the precordial area, is definitely harmful; it merely directs the patient's attention to his heart, and increases the difficulty of convincing him that heart disease is not the cause of his symptoms.

Drug Treatment.

The only drug of much value is bromide, and it can conveniently be combined with arsenic. Drugs of the "tonic" type may contribute to the sense of well-being, and may in this way be useful; probably none of them directly increase the patient's capacity for exercise. Various endocrines have been advocated, particularly thyroid, but there is no very definite evidence in their favour, and personally, I have never been convinced of their usefulness. It has been clearly shown by Lewis and his co-workers that digitalis is useless.

Treatment of Conditions likely to Aggravate the Symptoms.

It is not possible in a short space to give a comprehensive list of the various conditions which may aggravate the symptoms, much less to discuss their treatment. There are few diseases, even the mildest, whose effects are not reflected to some extent in the cardiovascular system, whether it is normal or not, and if observations are made on an individual's response to effort over a prolonged period, it is found that it is impaired by such trivial causes as a bad night or a slight headache. It is obvious, too, that a surgical disability, such as flat-feet, will cause an increase of pulse and respiration rate on exercise greater than normal by imposing a mechanical disadvantage on the muscles involved or by producing pain.

Certain conditions must, however, be particularly looked for, as being especially likely to contribute to the severity of the symptoms. Chief among these is septic absorption from such foci as the teeth, a nasal sinus, or even a "chronic appendix"; I have known cases where the eradication of a source of chronic infection has resulted in the disappearance of all cardiac symptoms without any further treatment. Any catarrh of the respiratory tract will increase breathlessness, but it is not so generally recognised what relief may be given by remedying structural conditions causing partial nasal obstruction.

Allusion has already been made to the important part played by defective vasomotor control, and the consequences of this are very apt to result from the effect on the vagus of any kind of gastric disturbance. The treatment of any coincident dyspepsia must, of course, vary in different cases, but as a rule these patients should be advised to drink between and not with their meals, to restrict carbohydrates and foods leaving a large undigested residue, such as cabbage or lettuce. Restriction in this respect, however, must not be too rigid in patients with a tendency to constipation. Such patients should also be warned against taking exercise directly after meals, particularly if they are liable to attacks of fainting. Visceroptosis is another abdominal condition that may require treatment, particularly if it is associated with a weak abdominal wall, which allows pooling of the blood in the splanchnic area, with consequent starvation of other parts of the body. Much discussion has arisen as to the part played by functional nervous disease in the production and aggravation of the symptoms, but probably most physicians would agree that while functional nervous disease may be associated with circulatory symptoms, circulatory symptoms by themselves rarely give rise to nervous symptoms other than anxiety about the state of the heart. It is important to assess the nervous factor at its proper value and to determine in every case: (1) whether the only nervous symptom is anxiety about the state of the heart; (2) whether the circulatory symptoms are primarily due to functional nervous disease, such as a general exhaustion state; or (3) whether the nervous symptoms are simply an associated condition, possibly produced by the same etiological factors as the circulatory symptoms. The answer to these questions must profoundly modify treatment, notably as regards the advisability of rest in bed; the management of the first has already been sufficiently indicated under the heading of "Reassurance"; the treatment of the other two is beyond the scope of this article.

Physician, Guy's Hospital.

SHORT COURSE OF INSTRUCTION FOR MAGISTRATES.—A short course of instruction for magistrates in connexion with their duties under the Lunacy and Mental Deficiency Acts was held at the Royal Sanitary Institute, under the auspices of the Central Association for Mental Welfare, from March 18th to 21st. It was the first course of the kind to be given in this country and aroused much interest, and although the number of justices attending was relatively small, it is felt that a beginning has been made in what may prove to be a work of very great importance. In all, 28 justices, men and women, took part in the course; the majority of these came from various parts of England, but one was from Nigeria and two came from South Australia. The instruction given consisted of eight morning lectures, supplemented by afternoon visits of small groups to various prisons, remand homes, mental hospitals, and other institutions. Sir Leslie Scott, K.C., M.P., gave the inaugural lecture on Legal Responsibility and Mental Deficiency; Dr. J. G. Porter Phillips gave three lectures on mental disorders, dealing especially with their medico-legal relationships; Dr. A. F. Tredgold dealt with the subject of mental deficiency in three lectures, dealing in detail with the subject of defective delinquents; and Dr. F. C. Shrubsall gave one lecture on Legal Administration under the Mental Deficiency Act. It was felt that the course proved a means of giving valuable information on the subjects of lunacy and mental deficiency, thoroughly justifying the new departure, and it is hoped to repeat it at a later date. Information as to future courses may be obtained from the Hon. Secretary, Central Association for Mental Welfare, 24, Buckingham Palace-road, S.W.1.

---

[1] The rate is reckoned by counting the pulse for the first quarter minute after exercise and multiplying the result by four.

Special Articles.

THE LEAGUE OF NATIONS:

FIRST SESSION OF THE PERMANENT HEALTH COMMITTEE.

THE League Health Committee met in Geneva from Feb. 11th to the 21st. This was the first meeting of the Health Committee of the permanent Health Organisation that was formed at the end of last year. At this meeting rules of procedure were adopted, providing for regular sessions twice a year, for the formation of temporary or standing subcommittees, and for the use of the services of experts in connexion with a meeting of any of these committees or of the Health Committee itself. Thus the organisation is rendered elastic and every opportunity afforded for establishing contact with national health administrations or private organisations working on the same subjects.

Dr. Th. Madsen, head of the Copenhagen Serum Institute, and formerly chairman of the Provisional Health Committee, was elected chairman of the Permanent Committee. The President of the Advisory Council, who is ex-officio a member of the Health Committee, was also, it was decided, to be ex-officio Vice-President of the Health Committee, in order to ensure close contact between the Office International d'Hygiène Publique and the Committee. Dr. Velghe, head of the Belgian Health Service, at present holds this office. In view of the increase of work and responsibility connected with the Health Organisation, it was decided to have two further Vice-Presidencies, to be held for one year without re-election, thereby ensuring rotation among the members of the Committee. Sir George Buchanan, who was Vice-President of the Provisional Health Committee, was elected, as was Surgeon-General H. S. Cumming, chief of the United States Public Health Service. The Committee also nominated three out of the four assessors which it is, by its constitution, allowed to select. The final appointment rests with the League Council. The three assessors chosen are Dr. Chodzko, former Minister of Health of Poland; Dr. Bernnard Nocht, Director of the Hamburg Institute of Tropical Diseases; and Dr. Alice Hamilton, of Harvard University Medical School.

The members of the Health Committee are at present:—

France.—Prof. Léon Bernard, Chair of Medicine, University of Paris; Dr. L. Raynaud, Inspector-General of the Algerian Health Service.

Great Britain.—Sir George Buchanan, C.B., M.D., Senior Medical Officer, British Ministry of Health.

Switzerland.—Dr. H. Carrière, Director of the Federal Health Service.

Brazil.—Dr. Carlos Chagas, Director of the Oswaldo Cruz Institute.

Poland.—Dr. Chodzko.

United States.—Surg.-General H. S. Cumming, Chief of the Public Health Service; Dr. Alice Hamilton, Harvard University Medical School.

Egypt.—Dr. A. Granville Pasha, President of the Maritime Health Board.

Holland.—Dr. Jitta, President of the Board of Health.

Portugal.—Prof. Ricardo Jorge, Director-General of Public Health.

Japan.—Mr. Shiko Kusama, Japanese Office for the League of Nations (until appointment of Japanese member).

Italy.—Dr. A. Lutrario, Director-General of the Health Administration; Prof. Ottolenghi, Siena University.

Denmark.—Prof. Th. Madsen, Director of the State Serum Institute.

Peru.—Dr. P. Mimbela, Chair of Medicine.

Germany.—Prof. B. Nocht, Director of the Hamburg Institute of Tropical Medicine.

Spain.—Prof. Gustave Pittaluga, Chair of Medicine, Madrid.

Belgium.—Mr. O. Velghe, Director-General of the Health Service.

The Work of the Committee.

From the point of view of work this session was the seventh meeting of the League Health Committee and continued the work already undertaken by the Provisional Committee. One of the most important subjects, and a fundamental task of the Health Organisation as a whole, is the development of the service of epidemiological intelligence and public health statistics.

Epidemiological Intelligence.—Thanks to the financial aid of the Rockefeller Foundation, it has been possible greatly to extend this work, so as to make it embrace most of the countries of the world. Plans are being laid to "speed up" the receipt of information from the various national health administrations, by the substitution of cable despatches for notification by post. In other ways the service is being organised so as to make it fulfil its grand purpose—maximum usefulness to the national health administrations.

Interchanges of Public Health Personnel.—The system of bringing together picked men from the different health administrations and enabling them to study the sanitary organisation of one or two countries or, in the case of specialists, of the way a certain disease is dealt with in several countries, was reviewed at the present session and plans laid for the year 1924. The system of interchanges has now been in existence some 15 months and is beginning to assume permanent and organised lines. For one thing, it has now been possible to prepare the time-table and details well in advance and to issue the programme of the interchanges for 1924 in the form of a printed handbook. The national health administrations in whose countries the interchanges are taking place are now also profiting by the experience gained in the past to perfect the arrangement of the interchanges, and several have begun in this connexion to issue handbooks on various aspects of their national health service, as well as short, general accounts of the health legislation and administration of their countries. Moreover, candidates are now selected well in advance and taken so far as possible from "strategic" posts in their respective health administrations, thereby making certain that the maximum benefits will accrue from the experience gained in interchanges, and that the candidate will be prepared for the work he is to do.

The Far Eastern Report.—The Health Committee, in order to extend its service of epidemiological intelligence to the Far East, as proposed in the report of the Mission sent to the Far East in November, 1922, has recommended to the League Council that an epidemiological intelligence office should be set up at some convenient port in the Far East, for the purpose of collecting and communicating periodically information as to the incidence and development of infectious diseases, particularly in ports and their vicinity. The report embodying the findings of the Mission to the Far East, and particularly the recommendation as to a sanitary convention between Far Eastern States, will be communicated to the Governments concerned for their observations. The replies of the Governments will subsequently be studied by a special subcommittee.

The Epidemic Commission.

The Health Committee took note of the fact that the special emergency work of the Epidemic Commission in Poland and Greece was now concluded, and that the activities of the Commission were being turned more and more into the channels of inquiry and investigation which are part of the normal rôle of the Health Organisation. Thus, while the budget of the Commission for its special work in Poland and Greece was made up from voluntary contributions, the last assembly voted a sum of Fr.50,000 on the regular budget of the Health Organisation to permit of the Epidemic Commission continuing its inquiries and epidemiological research work. It was decided that part of these funds should be used by the Commission for collaborating with the Russian health authorities in their epidemiological researches concerning the typhus epidemic that devastated Russia immediately after the war, as well as their inquiries into cholera. The Commission will also take part in investigating the epidemics of plague that have been reported from the Kirghiz Republic and Kalmuk Territory in Russia.

The Health Committee further expressed its satisfaction at the resolution of the fourth assembly, which, taking note of the fact that the Epidemic Commission's work during times of acute distress was likely to be arrested for lack of funds if the Commission were solely dependent upon voluntary contributions, recommended that the Council should in case of need study what resources could be placed at the disposal of the League Health Organisation to enable it "to intervene immediately through the intermediary of its Epidemic Commissioners in the event of sudden epidemic outbreaks of exceptional importance which might involve political consequences." This resolution was taken as satisfying to a large extent a request of the provisional Health Committee that a small fund should be kept by the League at the disposal of the Epidemic Commission for emergency work in preventing the spread of epidemic diseases where such measures were suddenly and urgently called for in the interests of the public health of the world.

Combating Malaria.

The Committee adopted the report of the subcommittee appointed last June to suggest methods of coördinating the campaign against malaria being conducted by a number of European States as a result of the aggravation of this disease in the years succeeding the war. A questionnaire drawn up in conjunction with malaria experts in the various countries is to be sent to the health administrations of European countries affected by malaria and the replies studied by a subcommittee composed of some members of the Health Committee and malaria experts coöpted from outside. In the light of the information received and other studies undertaken by the Health Committee a general report on malaria in the countries affected will be drawn up, and a programme of prophylactic measures outlined. The Health Committee will thus be in a position to furnish advice to Governments which consult it on the subject. Such advice has already been requested by the Albanian, Greek, and Persian Governments. One of the Epidemic Commissioners has already presented a preliminary report based on an investigation of conditions in Albania, and the Health Committee has now authorised a further and more extended investigation in both Albania and Greece, to enable it to furnish the Albanian and Greek Governments with the technical advice for which they ask.

The Persian Government's request, with which it is also hoped to comply, is more general and involves a sanitary survey of the country as a whole where, it is stated, a health service hardly exists and diseases of all kinds, particularly malaria and syphilis, but also cholera, influenza, bubonic and pneumonic plague, typhus and relapsing fever, small-pox, intestinal disease, trachoma, and typhoid are widespread. Cattle disease, notably anthrax, is also said to be very prevalent and the whole situation characterised as appalling. Health conditions in Persia are important to surrounding countries, such as Turkey, Mesopotamia, Russia, and India, and particularly so in view of the Moslem pilgrim routes from the Far East to Mecca.

Quinine Supplies.—A further aspect of the problem of malaria now taken up by the Health Section is the question of quinine supplies. At present the total quantity of quinine produced in the world is 600,000 kg. per annum, made in 14 factories. It is doubtful whether this quantity is sufficient for the world's needs in view of the grave increase of malaria since the war. Consequently, it is suggested that if inquiries and investigations by the League Health Organisation appeared to warrant such a course, a conference should be held of representatives of the health departments of countries in which malaria is an important and urgent problem, to consider the possibility of increasing the supply, and cognate questions.

Cancer Investigation.

The Health Committee decided to continue the work of the subcommittee for investigating the pronounced differences in certain forms of cancer mortality revealed by the vital statistics for England and Wales, Holland and Italy. This inquiry, which is being conducted in connexion with the big national inquiries, started in various countries, such as England and Italy, will, it is hoped, reveal to what extent the observed increase in cancer is real and how far due to better diagnosis, completer records, &c., as well as make possible comparisons between the statistics of different countries, and so widen the area available for the investigation of such matters in the future.

Anthrax.

A mixed subcommittee of the Consultative Commission of Industrial Hygiene of the International Labour Organisation and of the Health Committee will be formed to investigate the efficacy of procedures of disinfection.

Opium.

The Committee decided, on the basis of the report of its subcommittee, that 450 mg. per head per year might be considered a provisional maximum amount of raw opium (containing on an average 10 per cent. of morphine) for the medical and scientific needs of countries possessing a well-developed medical service. In any case, this figure, given at the request of the League Opium Committee, was considered to be only a rough guide for estimating what fraction of the present world production of opium could be considered necessary for medical and scientific purposes.

Standardisation of Sera and Biological Products.

The Committee noted that the system of checking the various national units of antidiphtheria serum by the international unit, of which supplies are kept at the Copenhagen Institute, was working well, and that this institute had already tested the American, British, and German units and found them identical. Final agreement concerning a unit for tetanus antitoxin is now in sight, and the unit proposed is half the existing American unit. Investigations of dysentery, pneumococcus, and other sera are still proceeding. It was decided to add the investigation of anthrax and Malta fever sera to the work already undertaken.

During the year 1923 very active research was carried on into the sero-diagnosis of syphilis, culminating in a conference at Copenhagen, where the directors of several institutes, accompanied by their technical assistants, engaged in joint laboratory work for the purpose of comparing and coördinating their methods and tests. In connexion with this work the Committee passed a resolution pointing out that, in view of the great social gravity of the disease, blood tests for syphilis should be carried out only by highly experienced workers in specially organised laboratories —that is, in conditions permitting careful checking of the results obtained and minimising the possibility of error. For the same purpose laboratories engaged in this work should keep in close touch with hospitals for venereal disease, so that laboratory tests could be checked by clinical symptoms. Finally, the Committee's resolution insists upon the importance of concentrating these tests in laboratories where they are made free of charge and that afford every technical guarantee to the health administration of the State concerned.

As regards biological products, the Committee noted that the work of standardising internationally the therapeutic value of this class of drugs was being developed methodically, and that particular attention was being paid to the question of how insulin is being put on the market in various countries.

THE ASSOCIATION OF SCANDINAVIAN SURGEONS.

IN the summer of 1893 the first meeting of the Association of Scandinavian Surgeons was held in Gothenburg, and since then the membership of this Association has grown to between 300 and 400, including practically all the most distinguished Scandinavian surgeons. The fourteenth meeting of this Association was held in Stockholm last summer, and its "Forhandlinger," or transactions, have been published this year by the Association's secretary, Prof. P. Bull, of Christiania. The meeting was held under the presidency of Prof. H. Forssner, of Stockholm; and Prof. T. Rovsing, of Copenhagen, was elected as his successor. The next meeting of the Association will be in 1925 in Copenhagen. The following three main subjects have already been chosen for discussion in 1925: (1) The treatment of acute osteomyelitis and its sequels, (2) the treatment of non-tuberculous diseases of the uterine appendages, and (3) tuberculosis of the kidneys and urinary tract. In connexion with the last-named subject, the Association has organised an inquiry among Scandinavian practitioners as to their experiences of urinogenital tuberculosis, and the information thus obtained will be discussed in 1925. Thanks to their polylingual accomplishments, Scandinavian surgeons derive their inspirations from many sources, and it would be as correct to call their surgery cosmopolitan as Scandinavian. But a perusal of the "Forhandlinger," which runs into several hundred pages, reveals so much evidence of independent research and progress on the part of Scandinavian surgeons that it would be obviously unfair to regard their work as being chiefly inspired from without. The three chief subjects discussed in 1923 were: (1) The treatment of fractures of the neck of the femur, (2) the place of Cæsarean section in obstetrics, and (3) the treatment of empyema.

Treatment of Fractures of the Neck of the Femur.

The two opening papers on this subject were read by Prof. R. Faltin, of Helsingfors, and Dr. U. Lindgren, of Upsala. The former dealt chiefly with the literature and the theoretical side of the subject, while the latter devoted himself mainly to the end-results obtained at his hospital. Prof. Faltin's paper was a scathing criticism of the attitude hitherto commonly adopted towards this group of fractures which have not been classified, but have been, in his view, lumped into one lot over which ignorant pessimism has brooded. Prof. Faltin's first step has been to draw up an elaborate scheme of classification based on Kocher's old clinical classification and supplemented by the modern evidence of the skiagram. The only good thing to be said of the attitude of the past generation of surgeons towards the treatment of this group of fractures is that few of them were pleased with it. It is at present difficult to ascertain where they went astray because their statistics do not, as a rule, discriminate between the various kinds of fracture of the neck of the femur. Though the treatment that is suitable for one kind may be quite unsuitable for another, Prof. Faltin urges as a general rule that the first aim should be the restoration of function, and this is generally best attempted by at once setting the fracture, the broken parts being restored as closely as possible to the normal position. This generalisation might seem a truism, but as late as 1921 the American, Whitman, wrote: "The ideal object of treatment, restoration of form and function, is rarely to be attempted or even sought. The first indication is to save life, the second to get union, the third to correct or diminish displacement." With regard to impacted fractures, whether they be lateral or median, Prof. Faltin is in favour of readjustment instead of leaving the impaction alone in the hope that it will form the starting point of satisfactory bony union. It is unwise to assume that an impaction is firm or, indeed, that it exists, for the X rays may suggest impaction, although the broken fragments are only lightly hooked in each other. As for the best form of immobilisation, there is much to be said in favour of Whitman's immobilisation in plaster with the limb fixed in the position of maximum abduction and inward rotation in certain kinds of fracture, the capsule of the joint being employed in this position to immobilise the fracture. This treatment is particularly suitable for young persons with median fractures. Prof. Faltin has little good to say of treatment with splints and bandages or early ambulant treatment based on the assumption that there is little to be gained by prolonged immobilisation.

Dr. Lindgren's paper showed that, according to earlier publications, the mortality from this group of fractures, subjected to different kinds of treatment, ranged from 7 to 31 per cent., the "good" results ranging from 9 to 89 per cent., a width of range suggesting that the word "good" was not used with a uniform meaning. Dr. Lindgren's own material consisted of 95 cases, 21 of which terminated fatally. Of the surviving 74 patients, practically all were re-examined, and as a result of this re-examination Dr. Lindgren comes to the conclusion that, provided the patient is not too old and infirm, active, but not operative, treatment should at once be instituted, the displacement of a median fracture being exactly corrected, and the limb being put up in plaster in a position of inward rotation and great abduction. In the case of lateral fractures, immobilisation may be effected by traction and extension instead of by plaster. In either case no weight should be put on the limb before six months.

In the discussion which followed, Dr. O. Löfberg, of Malmö, gave an account of 306 cases, in 212 of which correction of displacements had been followed by immobilisation in plaster, the limb being abducted and inwardly rotated. Of these 212 patients, 199 were discharged from hospital, and 188 were subsequently re-examined. In 83, or 67 per cent., there was osseous union, and the patients were able to walk perfectly or comparatively well.

Prof. J. Nicolaysen, of Christiania, traced the changes of fashion in the treatment of these fractures of late years, and he observed that the fashion of extension, which enjoyed its greatest vogue about 1900, had given poor results, as far as the median fractures were concerned. For the past 12 years he has adopted Whitman's treatment by immobilisation in plaster, but his results have not been good.

Dr. E. Perman, of Stockholm, illustrated the problem from the insurance and workers' compensation point of view. His material consisted of 111 cases investigated under the Swedish insurance scheme in the period 1918–1920. As many as 36 of the patients suffered no permanent invalidism, and only 51 were definitely incapacitated to a greater or less extent. In the remaining 24 cases the incident, from the insurance point of view, was not yet closed.

Several other speakers published statistics and related their experiences of this group of fractures, and it was evidently the general opinion of the meeting that the passive pessimism shown in the treatment of these cases in the past should be vigorously revised in favour of accurate diagnosis and classification, immediate correction of deformities provided the patient's vitality can stand the strain, immobilisation in plaster, and maintenance of this immobilisation for a very long time. This last point raised the question of hospital accommodation, while one speaker pointed out that the climate of the Scandinavian countries provides outbreaks of these fractures in epidemic dimensions.

Treatment of Empyema.

The opening papers on this subject were by Dr. P. N. Hansen, of Copenhagen, and Dr. Einar Key, of Stockholm. Many of the papers on the same subject read by other surgeons dealt with empyema statistics running into three figures, and the debate centred more and more on the comparative merits of the open and closed methods of treatment. Little was said of the closed method by suction in the first two papers, but in the discussion that followed Prof. T. Rovsing recalled the meeting of the Association in 1913, when he and Dr. Ove Wulff gave statistical evidence of the superiority of the closed over the open method, the death-rate being reduced from 24 to 14 per cent., the incidence of chronic empyema from 40 to 7 per cent., and the duration of treatment much reduced. The speakers who followed concurred on the whole with Prof. Rovsing, and even those who had found little difference in the mortality were inclined to prefer the closed method with suction through a Pezzer's catheter because of its comparative cleanliness, economy in dressings, and absence of that general discomfort entailed by the open method.

The Place of Cæsarean Section in Obstetrics.

The opening paper by Prof. K. Brandt, of Christiania, dealt with 50 Cæsarean sections performed between 1919 and 1922. In 16 cases the indication was a narrow pelvis, in 11 it was placenta prævia, in 6 it was premature detachment of a normally situated placenta, and in 5 it was eclampsia. In the remaining 12 cases a miscellaneous collection of indications existed. With regard to placenta prævia as an indication, he raised an ethical point which is of special interest to teachers. Being attached to a teaching hospital in which both midwives and medical students are trained, Prof. Brandt felt it incumbent on himself often to practise and teach those procedures which, though perhaps only second-best in a hospital, ought to be adopted by midwives and doctors in general practice. Under such extra-hospital conditions, it is obvious that Cæsarean section is seldom feasible. So at his hospital Prof. Brandt has practised and taught Braxton Hicks's version as the best treatment for most cases of placenta prævia. But the results obtained with Cæsarean section in 11 cases of placenta prævia were so good (no maternal and only one fœtal death) that he admitted the superiority of this procedure under suitable conditions over all others. His own views, and those of speakers who followed, left little doubt that, with only a few exceptions, Cæsarean section has gained much ground in the Scandinavian countries during the last few years.

Other Obstetrical Papers.

In addition to the full-dress discussion on Cæsarean section, papers were read on several other obstetrical subjects. Prof. Brandt pleaded for the identification of senile pyometra with cancer of the uterus, and for the routine early removal of the uterus on this indication without the wasting of time entailed by curetting and cauterising. In the past he had often committed this error, finding out too late that an overlooked malignant growth had extended rapidly after his palliative tinkering. In another paper he ridiculed, with the support of statistics, the tendency of German obstetricians to regard 2000 g. as the weight level below which new-born infants cannot be considered viable. Of 348 living infants weighing 2000 g. or less at birth, he had found that 117, or 33·6 per cent., had died within 14 days, but the remainder had been discharged from hospital in perfect health and with every prospect of growing up. A statistical paper by Dr. O. A. Boije, of Helsingfors, was a defence of plugging the uterus for post-partum hæmorrhage and a refutation of the teaching that a tampon in the uterus promotes infection. In 114 out of 11,442 confinements he had plugged the uterus for post-partum hæmorrhage, and none of these cases had terminated fatally. The fact that they showed a comparatively high puerperal morbidity (13·1 per cent. as compared with 5·3 per cent. for all the confinements) might well be traced to other factors than the plugging—i.e., to the atony of the uterus, which in itself favours retention and sepsis, and to the frequent use of forceps, which had been applied in 27·2 per cent. of the cases treated by plugging. A paper by Dr. B. Lundqvist, of Stockholm, dealt with the conduct of labour delayed by primary uterine inertia. The chief lesson of his statistics was that, when the membranes have ruptured, the sooner labour is hastened artificially by forceps the better, provided dilatation has proceeded far enough for this purpose.

Other Surgical Papers.

The following list will give some idea of the wide range of the subjects discussed: Sauerbruch's artificial hand, the treatment of Pott's disease and of congenital dislocation of the hip in adults, bone transplantation, lymphogenic, metastatic osteitis, the treatment of osteomyelitis, the pathogenesis of torticollis, Lane's osteosynthesis, Kielland's obstetric forceps, the genesis of tar cysts of the ovaries, supernumerary breasts, idiopathic dilatation of the œsophagus, the pathology of anal fistula, sarcoma of the stomach, the surgical treatment of trigeminal neuralgia, the diagnostic value of Wohlgemut's diastase reaction in acute diseases of the pancreas, and the operative treatment of deformities of the lower jaw, the diagnosis of intestinal obstruction by gall-stones.

The list may be further extended by valuable discussions upon the stopping of brain cysts with fat grafts, periarterial sympathectomy, operations for free foreign bodies in the posterior portion of the knee-joint, laxatives and restrictions of diet before and after operations, traumatic chyloperitoneum, the mobilisation of joints, nitrogen retention and excretion in the subjects of hypertrophy of the prostate, and torsion of the testicle. We have also such questions considered as the reason why torn and crushed nerves heal less satisfactorily than clean-cut nerves, the topical diagnosis by exclusively clinical methods of chronic ulceration of the stomach and duodenum, the value of basal metabolism investigations in Graves's disease, the clinical diagnosis of this disease, the prophylaxis of post-operative retention of urine, the value of total resection of the bladder for carcinoma and of the spleen for pernicious anæmia, and the early diagnosis of embolism of the renal arteries.

The papers and the discussions thereon are published in one or other of the Scandinavian languages, and for surgeons unfamiliar with these languages, but conversant with French and German, as well as English, much of the information in these "Forhandlinger" will be available when some of their contents are again published in one or other of the Scandinavian *Acta*.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Dick Test.

LAST year Drs. George F. and Gladys H. Dick reported the successful inoculation of scarlet fever into two out of ten volunteers.[1] The organism used on that occasion was a particular strain of streptococcus. Now using a filtrate of this same culture they claim to be able to determine susceptibility to scarlet fever in exactly the same way that the Schick test determines susceptibility to diphtheria. An intradermal injection of a suitable dilution of this filtrate was observed to yield the following results: In persons who gave no history of having had scarlet fever 41·6 per cent. were positive (i.e., susceptible); 65 convalescents from scarlet fever were either entirely negative or else very slightly positive. It was further discovered that the injection of serum from convalescent patients into normal individuals inhibited the reaction whether the serum was given previously or at the same time as the inoculation of the specific filtrate. In two instances in which it was possible to observe the test before and after an attack of scarlet fever it was found to give a positive reaction in the former and a negative reaction in the latter case. These observations are somewhat out of harmony with the research of other investigators that had tended to incriminate a filtrable virus, but the results obtained already are sufficiently important to call for a confirmation or contradiction by other immunologists.

---

To Control the Sale of Biologic Products.

On Feb. 28th a Bill was introduced into Congress to amend the Act of 1902 "to regulate the sale of viruses, serums, toxins, and analogous products." The amendments are naturally in the sense of strengthening this Act, which was perhaps rather in need of more rigid enforcement. The Secretary of the Treasury is empowered to refuse a licence to manufacturers if in his judgment the public interest would thereby be enhanced. No packages may be sold unless either an official standard or test has been established, or else the words "No U.S. Standard of Potency" shall appear in plainly legible type on the outside label or wrapper. No product shall be licensed which bears a deceptive label. Whether or no all these conditions can be enforced it is not easy to judge, but it is satisfactory that attention should be drawn again to the importance of standardising sera and vaccines not only in the United States but throughout the world.

Explosion of Anæsthetics.

The adoption of ethylene gas as an anæsthetic was announced more than a year ago. Since that time its use has spread gradually to most parts of the United States. Last week there was reported from the Union Memorial Hospital at Baltimore an accident which draws attention to a possible danger in the use of this anæsthetic, at any rate when administered with nitrous oxide. In this case the ethylene had been superseded for some reason by laughing gas, though at the time of the explosion the latter was turned off. A carbuncle had been excised and the surgeon was cauterising the wound with a platinum cautery. The patient died an hour after the explosion, death being attributed to pulmonary hæmorrhage. The anæsthetist's face was slightly burned and his hair singed, but no one else in the room received any injury. There are obviously explosive possibilities in this mixture of gases which should lead to caution in their use.

A MODEL SCHEME FOR A DIPLOMA IN PSYCHOLOGICAL MEDICINE.

As long ago as 1910 the President of the Medico-Psychological Association of Great Britain and Ireland addressed a letter to all universities and other examining bodies, urging the necessity for facilities being provided for post-graduate teaching in psychological medicine at all medical schools, and for the granting of a special diploma to candidates after examination, as had already been done with such conspicuous success in public health and tropical medicine. Largely as the outcome of that letter, diplomas in psychological medicine, or psychiatry, have been created at many universities and colleges, and definite progress has been made in the better systematic and scientific training of medical officers serving in mental institutions and others engaged in psychological medicine. Much, however, remains to be done. Not until every centre of medical teaching has adequate facilities for tuition in psychological medicine in the shape of a department or clinic in psychiatry can the treatment of disorders and diseases of the mind rise to the level of that of physical disorders and diseases. The Council of the Association, having regard to recent developments of psychiatry and practical experiences already gained in this matter, has prepared, through its committee on Post-graduate Teaching and Diploma in Psychological Medicine, a revised scheme of post-graduate work and subjects, which it is considered would constitute a suitable course for a diploma in psychological medicine. Its provisions are as follows:

1. The candidate must be already a registered medical practitioner.

2. The candidate may present himself for examination on the subjects detailed under Part I. of the curriculum (see para. 4) immediately he has concluded the prescribed course of instruction or can produce such other evidence of diligent study of the subjects to be examined upon as may be demanded. Part I. must be passed save by special permission at least three months prior to entering for examination on Part II. of the curriculum.

3. The candidate may not present himself for examination on the subjects detailed under Part II. of the curriculum (see 4) until he has been a registered medical practitioner for not less than two years. He must, subsequently to qualification, have been in the practice of an approved mental hospital for not less than two years, or have attended for six months at a hospital, mental or general, for clinical instruction in psychological medicine, and subsequently have held a resident appointment at an approved mental institution or mental wards of a general hospital for not less than six months. In both cases he must produce a certificate from a recognised source that he can apply his theoretical knowledge and has practical acquaintance with, and is well and adequately versed in, the current clinical methods of examination and treatment of nervous and mental disorders. In the case of mental deficiency the certificate should include a practical knowledge of the various intelligence tests and other methods of ascertaining the degree of mental defect. He must also produce evidence of having attended, subsequently to qualification, courses of lectures and demonstrations, or such other evidence of diligent study of the subjects upon which he presents himself for Part II. of the examination, as may be demanded.

4. *Curriculum.*—Part I.: (*a*) Anatomy, histology, and physiology of the nervous system, including the autonomic system. Anatomy and physiology of the endocrine glands. Chemistry and cytology of the cerebro-spinal fluid. (*b*) Psychology, systematic and experimental. Part II.: (*a*) Morbid anatomy, histology, and pathology of the systems mentioned under Part I. (*a*). Post-mortem and laboratory technique. (*b*) Neurology and clinical neurology. (*c*) Psychiatry (including the psycho-neuroses), clinical psychiatry and the medico-legal relationships of mental disorders and mental deficiency. In addition, the candidate for Part II. will need to show special knowledge of any one subject, to be selected by him from the subjects comprising Part I. or Part II.; or may choose to be examined in any one of the following subjects: (*d*) Mental deficiency and the mental disorders of childhood and adolescence, and the duties of school medical officers in relation thereto. (*e*) Bacteriology as applied to mental and nervous disease. (*f*) Psycho-pathology and psychotherapy. (*g*) The principles of diet, vitamins, and basal metabolism, and their application. (*h*) Eugenics, and vital statistics. (*i*) Criminology and the jurisprudence of criminal responsibility.

5. The diploma, by request, may be endorsed that special knowledge has been shown in the subject selected.

6. It is suggested that any compulsory attendance at lectures and demonstrations and clinical courses should be limited to the subjects detailed for Part II., and that the course for Part I. or Part II. should not exceed eight weeks.

The Association is fully aware that any action taken will need to be in line with the established practices and traditions of particular universities or examining bodies, but suggests that such bodies may give careful consideration to this model scheme.

MUNICIPALISATION OF MILK-SUPPLY IN MANCHESTER.—The Manchester Labour Party has prepared a report on the municipalisation of the city's milk-supply, to be brought before a conference to be held this month. The facts and arguments in this report are largely taken from a review written in 1920 by the present Lord Mayor when acting as chairman of the public health committee. In view of the deplorable condition of Manchester milk, together with the disastrous results on the young life of the city, the suggestion is to take the whole sale and distribution of milk out of private hands and place them under the jurisdiction of the city council. Unified control with a monopoly of sale would, it is alleged, give powers of inspection from the farm to the consumer, eliminate overlapping, and reduce cost. Other points in the programme are:—(1) Adequate inspection of farms in the rural areas, with compulsory drainage of shippons. (2) Establishment of country depôts where the milk can be strained, cooled, and bottled. (3) Special railway facilities; fleet of transport motors. Use and extension of tramways. (4) Milk centres in the city, to which the milk shall be directly consigned, from which it will be delivered to the consumer by light handcarts with compartments to hold the bottles. (5) Shops for the serving of customers, to be used as depôts for the replenishment of the dandies. Dairy produce made from the surplus milk at the country depôts to be sold. (6) Existing dairymen to be compensated.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. E. Moxon-Browne has been appointed senior medical officer of the light cruiser *Concord*.

The following appointments have been notified: Surg. Capts.: H. C. Whiteside, to the *Ganges*, for R.N. Sick Quarters, Shotley; L. M. Morris, to the *Victory*, for Haslar Hospital; and T. Creaser, to the *President*, for hospital course. Surg. Lt.-Comdr. S. R. Johnston, to the *Britannia*, for sick quarters, R.N. Barracks, Dartmouth.

ARMY MEDICAL SERVICE.

ARMY RESERVE OF OFFICERS.

Capt. N. M. Goodman, late Reg. Army Res. of Officers, Worc. R., to be Capt.

MILITIA.

Capt. E. A. Wilson to be Maj.

TERRITORIAL ARMY.

Capt. J. R. Griffiths (late Cheshire R.), to be Lt., and relinquishes the rank of Capt.

Lt. F. W. Martin to be Capt.

Lt. A. T. Sloan resigns his commn. and is granted the rank of Capt.

Capt. W. T. Gardiner from Gen. List to be Capt.

Supernumerary for service with O.T.C.—Maj. A. M. H. Gray to be Lt.-Col.; Maj. F. A. E. Crew to be Lt.-Col; and Capt. (Local Maj.) C. F. Searle to be Maj.

INDIAN MEDICAL SERVICE.

Col. R. Heard, K.H.S., has been selected for the appointment of Surgeon-General in Bengal, in succession to Maj.-Gen. B. H. Deare, C.I.E., K.H.S.

Majs. W. F. Brayne, S. W. Jones, J. Anderson, and G. G. Hirst to be Lt.-Cols.

MENTIONED IN DESPATCHES.

A *London Gazette* notice, dated March 28th, states that the name of the undermentioned officer is to be added to those brought to notice for distinguished and gallant services and devotion to duty by Lieut.-Gen. Sir J. G. Maxwell, commanding the Forces in Egypt, in his despatch of March 16th, 1916—namely, Maj. G. Hall, R.A.M.C. (T.F.).

THE NAVY AND DENTAL HYGIENE.

Attention is called in recent Fleet Orders to the importance of dental fitness. Arrangements are already in existence for the treatment by civilian dental surgeons of naval personnel where no naval dental officer is available at Army and Air Force dental centres. Dental officers will, it is stated, supplement individual instruction by lectures to patients on Oral Hygiene

TERRITORIAL ARMY NURSING SERVICE.

Regulations were issued with the Army Orders for February in regard to the Territorial Army Nursing Service, of which Queen Alexandra is president. The Service consists of the Matron-in-Chief, 23 principal matrons (4 in London, 2 in Glasgow, and 1 in Aberdeen, Edinburgh, Newcastle, Leeds, Sheffield, Manchester, Liverpool, Lincoln, Leicester, Birmingham, Oxford, Cambridge, Cardiff, Bristol, Portsmouth, Plymouth, and Brighton respectively), matrons, assistant matrons, sisters, and staff nurses. A candidate must be between 23 and 35 years of age, must be single or a widow, of British parentage or a naturalised British subject, and must possess a certificate of not less than 3 years' training in a civil general hospital of not less than 100 beds or a Poor-law infirmary recognised by the Ministry of Health as a nurses' training school. Senior members will be liable to be called up periodically for training in a military hospital, when they will receive army pay and allowances. On mobilisation members of the service will receive pay, according to rank corresponding to that of the Q.A.I.M.N.S.

DEATHS IN THE SERVICES.

Sir Walter J. Buchanan, K.C.I.E., I.M.S. retd., who was Inspector-General of Prisons in the Bengal Presidency from 1902 until 1919, died on March 23rd at the age of 62. He graduated in Arts and Medicine at Trinity College, Dublin, in 1887 and entered the Indian Medical Service in the same year. He served in the Chin-Lushai Expeditions, 1889–90 (medal with clasp), and retired with the rank of Lt.-Col. He edited the *Indian Medical Gazette* at Calcutta from 1899 to 1919, and was the author of a manual of Jail Hygiene.

Correspondence.

"Audi alteram partem."

CLINICAL RESULTS IN DEEP X RAY THERAPY.

To the Editor of THE LANCET.

SIR,—A consideration of the discussion on this subject at the Royal Society of Medicine[1] might easily give rise to a pessimism not, I think, fully justified. Some of the speakers—and among them one who had formerly been most enthusiastic—were of opinion that the percentage of successes by modern methods was but little greater than that obtained some years ago. The term "modern methods" was intended to refer chiefly to the Erlangen technique. It is, however, only fair to point out that the chief claim from this clinic was made concerning only one special form of cancer—namely, carcinoma of the cervix uteri; and then only with regard to early cases such as are, in this country, invariably operated on. If the public in Great Britain came to believe that the high percentage of "five-year" cures thus claimed (75 per cent., I think) could be obtained by the application of their method to other forms of cancer not at an early stage, this was no fault of the Erlangen authorities. The admitted fact that the treatment caused very considerable general disturbance led me from the first to regard it as unsuitable, at least in the single dose form, for advanced cases, and still less applicable for use as an aid to surgery. With respect to the latter, Mr. Sampson Handley—who is certainly the last person who could be accused of bias against X rays—said he was not sure that "deep X ray therapy" (by which he meant the massive dose method) was the sort of help the surgeon would ask. This attitude is not to be wondered at. For the surgeon must oppose anything which reduces his patient's vitality. He may reasonably ask one or both of two things from the radiologist: (1) that an inoperable case should be rendered operable; (2) that something be done to reduce the likelihood of recurrence after operations. He also requires that these things be accomplished without in any way depressing the patient. If, on the contrary, the latter can be made more fit in the process he is duly grateful.

Now, as a matter of incontrovertible clinical expression, it is often possible to make an inoperable case operable by comparatively small doses of X rays given every other day for a few weeks. At the end of which time, if pain has been complained of, it is less; and the patient feels much fitter than when the treatment began. Often weight has increased. It is obvious that no one would make a statement such as this unless, as is the case with the present writer, he could, if required, produce surgical testimony to support it. We have, then, a technique which is beneficial to the general health and of proved efficiency as regards its effects on malignant growth. It would, therefore, appear rational to employ the same procedure as a prophylactic after operation. I have done so for 13 years with what I believe to be excellent results—although, of course, it is much more difficult to furnish proof of benefit under these circumstances.

So much for the use of X rays as adjuncts to surgery. When a case be wholly abandoned to the radiologist he may at times use more drastic measures. The chief thing which the Erlangen School has taught us in this country is that under certain circumstances it is desirable to concentrate X ray dosage into a few days rather than to spread it over weeks. To give a patient an 8 to 10 hour exposure in one day is not, in my opinion, at all desirable. I am glad to see that you, Sir, in your editorial comments, say that the divided dose is preferable owing to lessening of the strain on the patient.

---

[1] THE LANCET, March 29th, p. 649.

In the case of people who live at a distance, it is often very convenient for them to get their treatment over in a few days. But there are disadvantages. If the result appears to the patient very good—as in breast and pelvic cases it often does—she may delay her return until a recurrence develops, perhaps a year later. The question arises whether we ought not to provide some intermediate treatment directed to the maintaining of the general resistance, and, incidentally, securing that the patient is kept under observation. Fresh air, suitable diet, and possibly synthetic sunlight, may prove as valuable here as in tubercle.

I am, Sir, yours faithfully,

Harley-street, W., March 30th. F. HERNAMAN-JOHNSON.

CERTIFICATES OF INSANITY.

To the Editor of THE LANCET.

SIR,—From Dr. Ian D. Suttie's letter published in your issue of March 29th it is evident that he has misconstrued my letter in your previous issue. I asked whether medical superintendents of mental hospitals generally did not treat medical certificates as "confidential documents," and whether the general practitioner who made these certificates did not expect them to be treated as such. In other words, are they not of the nature of confidential statements furnished by one doctor to another? Dr. Suttie has implied that I advocate this on the grounds of shielding the medical man from the resentment of patients whom they have certified, but Dr. Macnamara, on the other hand, who has dealt with this matter in his letter of the same issue, conveys my meaning entirely, which is far removed from what Dr. Suttie suggests.

It may be unknown to some that within seven days of the patient's admission to a mental hospital statements made in the certificate of admission are carefully gone into during the examination of the patient without unnecessarily informing the patient from what source they have been obtained, and I can see no reason why the "perfect frankness" which Dr. Suttie suggests is wanting cannot be exercised in this matter. During my 18 years experience I have failed to meet with that lack of confidence which Dr. Suttie states exists between asylum medical officers and their patients, and I am sure this is no more lacking in mental hospitals than general hospitals, where one constantly meets with "fault-finders" and the discontented.

Another disadvantage that Dr. Suttie claims mental hospital patients suffer from is "lack of insight." This being part and parcel of the patient's mental state leading up to his certification I fail to see what benefit it would be to the patient to see what has been written on these certificates.

I am, Sir, yours faithfully,

Devon Mental Hosp., Exeter, March 31st. RICHARD EAGER.

A CRITICAL EXAMINATION OF PSYCHO-ANALYSIS.

To the Editor of THE LANCET.

SIR,—Dr. A. Wohlgemuth's entry into the sphere of medicine does not bring with it an impression of knowledgeable information. The well-known method of abreaction or the reviving of memories of painful experiences was practically unknown in this country before the war. The therapeutic value has since been demonstrated by a large number of English observers—the names of William Brown, Culpin, Forsyth, Prideaux, Stanford Read, and the late Dr. W. H. Rivers occur to me—and Dr. Wohlgemuth's reference [1] to one twenty-year-old foreign authority for the other side, although "especially emphatic," is not convincing even if the counting of heads has value in deriding controversy. Some of the workers above-named are not psycho-analysts, but they provide a wealth of observation, showing the need for a theory to convey the working of mental processes apart from awareness. I am not assuming that Dr. Wohlgemuth could not have found English authorities to support his contention, for the method of revival met with extraordinary opposition. The loss of memory was denied by some, the possibility of revival was denied by others, and its therapeutic value was attributed to "suggestion." At first sight the reason for this opposition is not clear, but when it is realised that if observations are correct, Freud's theories—even if not fully confirmed by them—must be seriously considered, then the opposition becomes comprehensible. Freud is a heretic, and no observation must be admitted that might strengthen the heresy, even if those who made them are not Freudians. If Dr. Wohlgemuth seeks clinical evidence which cannot be classed as "assertion," I recommend him to read Culpin's "Psychoneuroses of Peace and War" (Camb. Univ. Press). This writer is rather chary of theory except so far as his own observations demand it. I am, Sir, yours faithfully,

Wimpole-street, W., March 28th. ROBERT M. RIGGALL.

DICHOTOMY.

To the Editor of THE LANCET.

SIR,—I was, to put it mildly, surprised to see a report in the public press of a meeting of a provincial medical society at which the above subject was discussed and a resolution condemning the practice passed. In your issue of March 29th an article deals with the legal aspect of the practice.

The inference the public would naturally draw from these article is that such a practice is prevalent in the profession. Nothing could be conceived more calculated to impair or destroy the confidence of the people in their medical attendants. In my 40 years' work in the profession I never had even dreamed of the possible prevalence of such a state of affairs.

I trust in a future issue of your invaluable paper you may be able to deal with the topic in such a way as may remove all apprehension as to the existence of "dichotomy," in the manner suggested in the reports I have mentioned, from the minds of the public and of Yours faithfully,

Blackpool, March 29th, 1924. LEONARD MOLLOY.

*** No suggestion was made that the practice occurred with any frequency in this country. But the difficulty has been notorious elsewhere, as our special correspondents have pointed out.—ED. L.

DOMINIONS MEDICAL HOSPITALITY COMMITTEE.

To the Editor of THE LANCET.

SIR,—We have been instructed to ask members of the medical profession to assist this committee by offers of personal help. The circumstances of the formation and constitution of the committee have been fully explained in *The Lancet* and in the *British Medical Journal*.[1] The committee includes the President of the Royal College of Physicians, the Vice-President of the Royal College of Surgeons and Vice-Chancellor of London University, the Master of the Society of Apothecaries, the Presidents of all the Medical Societies of London, representatives of the Naval, Military, and Royal Air Forces, and of all the Dominions and Colonies. If any members of the medical profession in or near London are prepared to offer personal hospitality, we should be much obliged if they would inform us. Suggestions will be welcome. We are instructed to say that the committee would be grateful for any kind of hospitality, whether it take the form of accommodation for a short period, or of receptions, dinner parties, and the like.

The hon. secretaries will be glad to coöperate with the hosts in any way that may be of use, and will give any particulars possible. Offers should be addressed to the hon. secretaries, 94, Harley-street, W. 1.

We are, Sir, yours faithfully,

A. E. MORTIMER WOOLF, }
E. T. C. MILLIGAN, } Hon. Secretaries.

March 31st, 1924.

THE TESTIMONIAL TO DR. BRACKENBURY.

To the Editor of The Lancet.

Sir,—The long and untiring devotion of Dr. H. B. Brackenbury to the interest of the medical profession, culminating in his recent presentation of the case for insurance practitioners before the Court of Inquiry, has given rise to a widespread feeling that the time is opportune for adequate acknowledgment of his unique services. In order to give material expression to this desire a Committee has been formed with the object of collecting a fund which will be applied in a manner to be decided at a later date, after consultation with Dr. Brackenbury.

Insurance practitioners, who more than all others are indebted to Dr. Brackenbury, will be approached through their panel committees, many of which have already taken the matter in hand and have promised contributions. The appeal, however, is a general one, and steps are being taken to bring the fund to the notice of various other professional organisations. No direct request will be made by this Committee to individuals, but the Committee will welcome contributions from any member of the profession who wishes to pay tribute to Dr. Brackenbury's immense labours.

All communications should be addressed to the honorary secretaries of the fund (of which the undersigned form the executive committee), and cheques should be made payable to the honorary treasurer, Mr. H. S. Souttar, at Room 17, 429, Strand, W.C. 2.

We are, Sir, yours faithfully,

H. G. Dain,
Chairman.
N. Bishop Harman,
Deputy Chairman.
H. S. Souttar,
Hon. Treasurer.

Peter Macdonald,
Hon. Secretaries.

"BLIND CÆCOSTOMY."

To the Editor of The Lancet.

Sir,—In a kindly review of the second edition of my book on "Acute Abdominal Diseases," published in your issue of last week, there is almost a complaint that I do not advocate that operation for acute intestinal obstruction to which the name of "blind cæcostomy" has been applied. Now I am not quite sure who is responsible for this title, but it seems to me that surgical practice should not be governed by phrases. Whatever the value of catch-phrases may be in political issues, I think we ought to abjure them in scientific circles. Cæcostomy is certainly a good operation where cæcostomy is indicated, but why apply the adjective "blind"? Such a cæcostomy is an example of blind surgery. We all know what ought to happen if the blind lead the blind, but in this connexion it is the patient who falls into the ditch!

In how many cases of *acute* intestinal obstruction is it possible to know before operation that the obstruction is below the cæcum? In those where an obstructing mass can be palpated in the course of the colon, and this is usually prevented by the distention of the bowel. Secondly, in those cases where rectal examination reveals the cause of the obstruction, and I would submit that the only common indication for cæcostomy in acute obstruction is the discovery of a growth in the rectum. If this be so, it is a scientific procedure and does not merit the name "blind." I freely admit that lives have often been saved by an opening in the small intestine where the actual site of obstruction has not been determined and the surgeon contents himself with draining a distended piece of small bowel, but the same technique does not apply to the cæcum unless it is enormously distended. Furthermore, it must have been the experience of other surgeons besides myself that in a case of growth of the large intestine, as well as in diverticulitis of the pelvic colon, small and large bowel obstruction have been present at the same time, due to the small intestine being kinked, and adherent to the large. In such a case cæcostomy without exploration would indeed be "blind," and this adjective would soon be applicable also to the patient. Catch-phrases make bad surgery.

I am, Sir, yours faithfully,
Joseph E. Adams.
Harley-street, W., March 31st, 1924.

A CASE OF PRIMARY DISLOCATION DUE TO BOXING.

To the Editor of The Lancet.

Sir,—A patient recently reported sick, and was found to be suffering from a typical dislocation of the right shoulder. He stated that it took place whilst he was making a forward right stroke, boxing. He is a very muscular man, and the dislocation could not be reduced without an anæsthetic.

The points of interest are: (1) The uncommon cause of the dislocation; (2) the fact that the dislocation was a primary one. As the patient's shoulder-joint was not X rayed before the lesion was reduced, I am not certain whether it was of the subglenoid or the subcoracoid variety.

I would be interested to hear if any of your readers have met with a similar accident under similar circumstances.—I am, Sir, yours faithfully,

Brighton, March 26th, 1924. W. S. Crosthwait.

ITALIAN LABELS ON PROPRIETARY MEDICINES.

To the Editor of The Lancet.

Sir,—Our attention has been directed to your issue dated Feb. 2nd, on p. 256 of which, under the heading Secret Remedies, Formulas Disclosed by the Makers, you include what purports to be the formula of Guy's tonic. In the introductory paragraph it is suggested that this formula has appeared upon bottles of Guy's tonic sold in Italy, and that although the formula may not be the right one, the composition as stated is that disclosed by the makers themselves.

We desire to advise you that the exact composition of Guy's tonic has not been disclosed by ourselves to anybody, nor have we directly exported goods to the country mentioned. We understand that it is the custom of some distributing firms who import proprietary medicines into Italy to evolve a formula for the sole purpose of getting the goods through the customs. Consequently, these formulas may often bear very little relation to the actual ingredients. If this has been done in respect of Guy's tonic, you will agree that, as proprietors, we are not responsible, and in so far as your paragraph suggests that the formula you publish is that given by ourselves, or even authorised by us, it is contrary to fact and does not confirm or otherwise the alleged composition of Guy's tonic as published in Secret Remedies.

We are, Sir, yours faithfully,
March 20th, 1924. Guy's Tonic, Limited.

Presentation to Dr. F. W. Collinson.—Following a dinner at the Bull and Royal Hotel, Preston, on March 25th, Dr. F. W. Collinson was presented with his portrait in oils, painted by Mr. W. W. Russell, A.R.A., and an illuminated address on behalf of 80 medical men of Preston and district. The address, beautifully bound in dark-blue morocco, was inscribed on vellum, with a replica of the portrait on the title page. Below the portrait was the following inscription:—Frederick William Collinson, M.D. Edin., M.R.C.P. Lond., F.R.C.S. Edin., senior house surgeon 1887–1889; honorary surgeon 1889–1923; hon. consulting surgeon, 1923; hon. secretary medical board 1901–1924; hon. librarian Brackenbury Library, 1894–1924; vice-president Preston Royal Infirmary, 1923. The presentation marked the retirement of Dr. Collinson as senior surgeon from the medical staff of the Preston Royal Infirmary.

Obituary.

HETTY ETHELBERTA CLAREMONT, M.S. LOND., F.R.C.S. ENG.

WE deeply regret to record the death on March 27th of Miss Ethelberta Claremont, from broncho-pneumonia complicating typhoid fever. Born in 1892, she was the daughter of Mr. A. W. Claremont, J.P., and granddaughter of Claude Clarke Claremont, M.R.C.S. Eng., sometime public vaccinator for St. Pancras; and she belonged to a family that has given a number of medical men to the profession. Educated privately and at King Alfred School under Mr. John Russell, Miss Claremont began her medical studies at the London (R.F.H.) School of Medicine for Women and proceeded later to St. George's Hospital, where she was awarded the John Hunter gold medal. After a brilliant career as a student she took the Conjoint Diploma of the Royal Colleges in 1916, and the M.B., B.S. Lond. in the following year. At St. George's Hospital she held numerous appointments, including those of house surgeon, house physician, surgical registrar, resident anæsthetist, assistant curator of the museum, casualty officer, and assistant in the V.D. department. In 1920 she became a Fellow of the Royal College of Surgeons and then spent a year as voluntary resident assistant surgeon at the Zurich University Clinic, also visiting clinics at Vienna, Budapesth, Frankfurt, and Madrid. On her return to England she became surgical registrar to the London Temperance Hospital and was appointed surgeon to the Bermondsey Medical Mission Hospital, and she held the post of clinical assistant at the out-patient department of the South London Hospital for Women, and for a time at the female Lock Hospital. In 1922 she became a Master of Surgery in the University of London.

ETHELBERTA CLAREMONT.

As a surgeon Miss Claremont showed outstanding abilities and perseverance. Her skill as a diagnostician was great, but even more remarkable was her discernment of human nature. She was deeply concerned with the welfare of her patients, in whom she took a lasting interest. At the time of her sudden illness she was developing some original research work which will now be lost to medicine. Miss Claremont had more than average linguistic ability. She was athletic, possessing an exceptional physique and some experience of mountain climbing. She could walk 20 miles in a day. Her hobbies included carpentry, gardening, and music. The freshness and charm which attracted people to her were the visible signs of an inward healthiness of body and mind.

To Miss Claremont's qualities of heart and head we have received a number of personal testimonies. Dr. Mary Scharlieb, after describing her record of professional work as one of which any young graduate might be justly proud, adds: "It shows how wide was her range of knowledge and how well she had succeeded in impressing her personality and her abilities on those who were best qualified to judge of them, her own immediate superiors and teachers. We all acknowledge the loss sustained by the medical profession in the premature and tragic death of this gifted and very charming young woman. I knew Dr. Ethelberta Claremont well from the time that she was a little girl, and always found her to be straightforward, honourable and unselfish."

Sir Humphry Rolleston writes: "The premature end of a promising career before there has been time to see its outcome is always distressing, and in the case of such a keen intellect and attractive personality as that of Miss Claremont is indeed deplorable. Coming to St. George's Hospital during the war, she held a number of resident appointments and then served as surgical registrar and assistant curator of the museum; I saw much of her work in the last post and came to respect her ideals and practical efficiency. With the highest surgical qualifications she had in her short professional life since then worked hard in several other hospitals, but the reward that honest devotion should have secured has been denied her and the profession has been robbed of a brilliant and promising member by the ruthless hand of death."

Miss Claremont had been recently a frequent and valued contributor to our editorial columns, and we join with her other friends and admirers in offering tribute of sympathy to her parents and family.

THE LATE SIR WILLIAM MACEWEN.

WE have received from a friend of the late Sir William Macewen, who also attended him in his last illness, the following appreciation:—

"On one of these recent days the writer stood, alone in the room, by the bedside of Sir William Macewen, when he lay, high on his pillows, enjoying a brief respite of peace and comfort from suffering. Quite suddenly and spontaneously, in his ordinary quiet and deliberate voice, he began to speak of Mr. Lister. That surgeon had brought into his class one day a book from which he read to his students extracts from a paper by Pasteur, in which the French chemist explained his view that putrefaction was due to the operation of living organisms. Mr. Lister had consulted an eminent chemist of the day as to chemical means by which such organisms might be destroyed on living tissues, and the answer he had received was that he could be supplied with a long list of such substances, but what their effect might be on the tissues it was for the surgeon to determine, but the chemist had added 'try carbolic acid.' These were days scarcely to be imagined or conceived by the surgical student of the present day, and death following amputation after amputation in melancholy and almost invariable sequence was disheartening to the last degree.

"William Macewen, a junior student of surgery in the Royal Infirmary at that time, was a witness to these events and a listener to these suggestions, and one morning, more than usually depressed by these events, he came out of the infirmary, and sat down on a bench to consider by himself whether he could continue to pursue a study which could show only such results, and whether he should not abandon the study of medicine. An elderly woman of the domestic staff passed him as he sat in gloomy contemplation, and, struck by his aspect, stopped in front of him and said, 'What's makin' ye sae sad the day, laddie?' To which he answered with a wave of the hand towards the hospital, 'Who could help being sad at these things.' To which the woman replied that it would be to more purpose to go back and try to mend them. The student went back, went back to a recent amputation, looked at the ligatures which projected in long ends from the wound. They looked dirty; he then had a look at the unused ligatures, which were made of hemp and kept in a jar, and they did not seem clean. He then asked and obtained permission to try if boiling would improve them, and from the ligatures he passed to the needles, and, without further request, passed to the instruments, with increasingly appreciable results; but he could not so secure the cleanness of the hands of the attendant who handled them all.

"The little monologue, of which the above is but the substance, was spoken in a clear quiet voice, without halt for fitting words, without delay of memory, as if the times, and occasions, and incidents stood out clearly in the speaker's mind as but things of yesterday, but the tale was unfolded with, for that speaker, a most unusual quiver of the mouth and moisture of the eyes. It was as if the speaker's mind travelled back down the long trail which he had followed, and saw, far down amid darkness and cloud of ignorance and noisome pestilence, the very spot and moment from which he had consciously and deliberately set forth on a determined road—the bitter, narrow path of commencement, full of hindrances and obstacles, the toilsome slow ascent, until at last he lay at rest upon the shining peak—content. There was no exultation in the quiet voice, no self-glorification in the calm narration, only a fullness of content at the assurance that the task he had, more than half a century before, set himself to do had been accomplished.

"This was the key to Sir William Macewen's character, the 'secret' of his life. He deliberately set before himself a definite purpose, not the quest of glory nor the amassing of riches, but the exposing of the causes of a type of disease that was a scourge to humanity and a scandal to surgery and their destruction. To this end everything was subordinated. For the causes were a mystery; they were as impalpable and invisible as they were malignant and apparently omnipresent. He began the task from the beginning; there was no science of bacteriology then, no charts of the region he set out to explore, no guide in the darkness he set out to illuminate. He had to devise his own methods, to forge his own instruments. He worked alone. He must have been gifted with remarkable powers of observation, a clear faculty of memory, and a firm will. But even gifts atrophy if unused, but his he developed to a high degree as implements for his purpose.

"Thus mere opinions and arguments founded on opinions left him cold. He wanted facts, and because a misinterpreted observation might easily lead widely astray, he wanted to observe the alleged fact for himself, and if it had any bearing on his pursuit to work out his own conclusions. Thus the very circumstances of the time and the nature of the pursuit led inevitably to a discarding of traditional views, to a mistrust of ordinarily accepted methods, and to a minute attention to detail in the devising of new ones. In his progress his mind advanced deliberately from one tested position to another; he refused to take mental leaps. As success attended his endeavour, and the prospect widened, the implications of his work went far beyond the goal for which at first he set out.

"The surgical student of to-day enters upon such a heritage of established fact, of clear principle, of proved method that it is scarcely possible for him to realise the ignorance and darkness out of which these have been evolved and the labour involved in the process. The search for the cause of surgical disaster, on the assumption that the cause is living, infinitely small and ubiquitous, inevitably laid under suspicion everything and every person in, on, and around, and the elimination of every possible source from which the cause could issue seemed almost an unattainable ideal, yet this was the ideal which the, as yet, unqualified junior student of surgery seemed already to conceive. But what a deep distrust of men and of things does this engender! What caution in the choice of human instruments no less than of material means! What testing of them all when chosen! If the full development and practically automatic observance of the aseptic technique have swept away these clouds of suspicion and mistrust with the ignorance and pestilence out of which they were begotten, they yet left their indelible stamp upon the man who, to accomplish their destruction, had submitted himself to their ordeal.

"Macewen's independence of judgment, keenness of observation, meticulous attention to detail, tenacity of purpose, caution in reaching conclusions, reliance on self were some of the weapons he took to himself for the warfare in which he engaged and to which he gave his life; they were the habiliments of his mind, the vestments of his spirit. Similar qualities characterised his friendship. He did not 'wear his heart on his sleeve for daws to peck at.' He was slow to give his friendship, for with it he gave his confidence, and here, too, mistrust had first to be dispelled, or, rather, fitness for trust had first to be established. His hospitality exhibited some of the same high quality. The discerning guest at his table could not fail to savour the harmony that pervaded the meal, and the fitness without ostentation of its service.

"Sir William Macewen would have made a poor politician; he would never compromise, though in less democratic days he might have made a rare statesman. In commerce he would have been a failure; he never bought in a cheap market, he gave always of his best, and often did not know whether he had received payment. Work was his religion; and the religion of his work was, 'Whatsoever thy hand findeth to do, do it with thy might.'"

SUSSEX PROVIDENT SCHEME.—This scheme for hospital benefits and additional medical services, to which persons are entitled by paying small sums in advance, made great strides during 1923. Fifty-six new groups were formed, and there was an increase in the number of subscribers to the extent of 2761, with a corresponding increase in the number of dependents of 4393, making in all a total increase of 7154 people entitled to the benefits. At the end of 1922 there were no groups outside Brighton and Hove, but at the end of 1923 there were 17; this number had been doubled since the advent of the current year, largely owing to the efforts of Major G. H. M. Fowler, who had been appointed by the Royal Sussex County Hospital as county appeal organiser and lecturer. The report presented at the annual meeting on March 19th showed that during 1923, 312 people received in-patient treatment for a period of 6520 days at a cost of £2786 3*s.* 11*d.*, and that 1037 people had made 5542 attendances for the various forms of specialised medical treatment at a cost of £448 15*s.* 6*d.*, making a total of £3234 19*s.* 5*d.* paid to the hospitals. The balance-sheet showed a small balance in hand proving, it was declared, that 12*s.* a year was the minimum subscription which could provide hospital treatment. Dr. Gordon Dill, the founder of the scheme, expressed the view that having successfully weathered three most expensive years, so far as hospital treatment was concerned, a larger balance would be shown at the end of the current year, by reason of the decrease in the hospital costs, notably in the case of the Royal Sussex County Hospital.

Medical News.

University of London.—At a meeting of the Senate held on March 26th, the Vice-Chancellor being in the chair, Mr. H. J. Waring was appointed to represent the University at the Imperial Social Hygiene Congress to be held at the British Empire Exhibition in May, 1924.

Lectures on Mental Deficiency.—A course of lectures on mental deficiency, supplemented by a course of clinical instruction, has been arranged by the University Extension Board in coöperation with the Central Association for Mental Welfare, to be held from May 19th to 24th. It is intended for qualified medical practitioners, and more especially for those who are engaged as certifying officers to local authorities under the Mental Deficiency Act, 1913, as school medical officers, or as medical officers of institutions, or who are otherwise definitely concerned with defectives. The course will be based on the requirements of the syllabus for the University of London diploma in Psychological Medicine. The University will grant a certificate of attendance to those who have attended the whole course regularly, taking both theoretical and practical work. Lectures will be delivered by Drs. A. F. Tredgold, F. C. Shrubsall, Cyril Burt, D.Sc., and Norwood East, and the clinical work will consist of visits to L.C.C. and other special schools for mental deficients. Registration fee, 10*s.* 6*d.*; fee for the course, £2 12*s.* 6*d.* All communications with reference to the course should be addressed to Miss Evelyn Fox, c/o University Extension Department, University of London, Imperial Institute-road, South Kensington, S.W. 7.

University of Manchester.—At recent examinations the following candidates were successful:—

Diploma in Public Health.

Beatrice L. Ellison, W. D. Hood, J. G. McKinlay, and Margaret Pownall.

Diploma in Psychological Medicine.

Part I.—L. C. F. Chevens, H. D. Cormac, T. W. Davidson W. J. Lynch, W. R. McGlashan, and C. B. V. Walker.

Queen's University of Belfast.—At examinations held recently the following degrees and diplomas were obtained:—

Doctor of Medicine (M.D.).

*John A. Smyth, †John H. Dunn, William E. Crawford, Eric A. Davison, John S. Dudgeon, and Samuel A. Powell.

Bachelor of Medicine, Bachelor of Surgery, and Bachelor of Obstetrics (M.B., B.Ch., B.A.O.).

First-class Honours.—Thomas J. Gibson.

Second-class Honours.—Wallace Linton and Matilda Matson.

Pass.—Isobel Alexander, Thomas V. Aronstam, James G. Bell, John E. Boyd, John L. Bradley, Margaret T. Clearkin, Thomas Craig, John S. Erwin, Elizabeth Fulton, John A. Gill, William D. Hamilton, William K. Hay, Elizabeth G. Henderson, James P. Henderson, David Kinley, Isabel Lindsay, Gerard B. McCloskey, Samuel McCormack, Helen F. McCrea, Violet McFeeter, William G. McKinney, Catherine McNeill, Jane A. D. Maclean, Edward Magee, John S. Malseed, Flora Richards, Gibson G. Smith, James Smith, John Stuart, Dorothy Watson, and Eleanor I. Wheeler.

Diploma in Public Health (D.P.H.).

Kenneth Cowan, George A. Dawson, Margaret R. Hanna, John J. Murray, John W. Orr, Mary E. Patterson, John Scott, and Jeanie Wilson.

Diploma in Dentistry (L.D.S.).

William A. McClelland.

* With Gold Medal. † With commendation.

University of Aberdeen.—At examinations held recently the following candidates satisfied the examiners:—

Degree of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).

With First-class Honours.—*Andrew M. Duthie.

With Second-class Honours.—Arthur M. Barron, †Charles Burnett, †William Greenlaw, †William Gunn, David P. Levack, Thomas D. Marr, †Mary S. Sutherland, †Gavin C. Taylor, †Charles W. Walker, and †William W. Walker.

Ordinary Degree.—Alexander Aberdein, William Adams, John H. Bell, Jeannie Benzie, Frederick J. T. Bowie, John Boyd, James Carrie, Laura D. Catto, William G. Cheyne, George S. Christie, William S. G. Christie, Thomas Clunie, Henry Clyne, James Cooper, William S. Coutts, James W. Craig, Charles L. C. Crowe, James Davidson, Sydney G. Davidson, Alexander W. Dockar, James K. Donald, Alexander Donaldson, Arthur W. M. Douglas, John W. Duncan, John F. Durno, Effie M. Duthie, Walter L. Esson, Leonard H. Eunson, Donald Farquharson, Rhoda G. Findlay, Nelly Flett, Alexander M. Fraser, Robert G. Fraser, Eric G. A. W. Fulton, John A. Gaiter, Edwin Garden, Robert U. Gillan, Daniel G. J. Gordon, James Gordon, James Grant, John K. Grant, Alexander P. Gray, John S. Harper, James W. Hay, James Henderson, Allan C. Hendry, Edward Hutcheon, James Innes, William J. Jack, William J. Leach, Mary R. Levack, John M. MacFarquhar, William H. J. McGillivray, Alexander H. Mackay, George W. M. Mackay, Harry A. Mackay, George D. Mackenzie, James McKenzie, Neil O. Mackinnon, John W. McKinty, Leslie G. McLean, †Duncan McLellan, Donald McLennan, Angus Macphail, Redvers G. Melvin, Betty Mitchell, George R. Morgan, †Alexander M. Morrice, †Alexander G. Mowat, James J. Munro, James W. Murdoch, William Niven, James H. S. Peterkin, William R. Pratt, Alexander F. Pringle, Francois P. S. Retief, Alexander Roy, Christina Russell, Robert A. Simpson, David Skinner, Gordon J. Smith, Gladys A. Spark, Robert J. Stephen, James G. Stewart, William Sutherland, George Swapp, Margaret A. C. Symon, Robert M. Thompson, Alfred Torrie, William Tweddell, James A. Whyte, Charles D. Wilson, and Maxwell C. Wright.

Diploma in Public Health (D.P.H.).

Helena M. Davidson, Marjorie I. Outram, and Gladys N. Watson.

* Completed Final Medical Professional Examination with much distinction.

† Completed Final Medical Professional Examination with distinction.

School of Physic, Trinity College, Dublin.—At examinations held recently the following candidates were successful:—

Final Medical Examination.

Part I.

Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.—C. R. Boland (high marks), N. Shapira (high marks), W. G. S. Maxwell, F. H. M'Kenna, H. Waters, E. S. A. Crawford, C. E. M'Causland, H. Tomkin, and M. Sherowitz.

Part II.

Medicine (M.B.).—L. E. J. Werner (high marks), R. Schaffer (high marks), C. J. M'Quillan, G. Robinson, W. R. Aykroyd, M. A. Gerrard, H. J. Hugo, M. D. Fox and Evaline E. Mooney (equal), W. J. Janse van Rensburg, L. C. Brough, R. R. D. Crawford, Lucy M. Joly, R. L. G. Proctor, W. A. Hopkins, K. F. Mackenzie, Eileen Brangan, Anne D. Dockrell, I. J. Isaacson, P. P. van der Merwe, S. Wigoder and G. A. Cowan (equal), W. A. Redmond, D. K. Lyons, E. C. Downer and J. J. Laing (equal), C. R. Hillis, Dorothy J. Booth, J. L. F. Steele and C. J. N. Loubser (equal), J. Morris, and A. L. Dobbyn and O. G. Wilde (equal).

Surgery (B.Ch.).—W. A. Taylor (high marks), L. E. J. Werner (high marks), F. C. B. L. B. Crawford, Lucy M. Joly, L. M. Bell, A. Hawthorne, Anne D. Dockrell, Norah M. Gilcriest, E. Harvey, R. E. Fausset and I. J. Isaacson (equal), Evaline E. Mooney, H. O'D. Burke-Gaffney and Bertha H. Lawler (equal), W. R. Aykroyd and C. J. N. Loubser (equal), R. Warnock, and S. W. Jamison.

Midwifery (B.A.O.).—T. W. May (high marks), D. L. Hemmingway (high marks), P. K. Dixon, M. Sless and W. D. Speedy (equal), Isidore Rosin, W. H. Coen, A. J. Mooney, J. Cussen, S. M'Dermott, S. E. Magowan and Isobel G. Smith (equal), F. M. Purcell, W. H. Maguire, J. Crawford, M. D. Fox, J. M. Johnston, J. L. Levingston, G. G. M'Farland, J. G. Maguire and A. B. Monks (equal), Agnes L. Kelly and C. Lord-Flood (equal), M. J. Bradlaw, C. R. Moore, A. J. Head, W. J. van Zijl, and C. Wilson.

Diploma in Public Health.

Part I.

Chemistry, Bacteriology, Physics, and Meteorology.—G. Bewley, N. M'I. Falkiner, B. W. D. Fayle, A. Darlington, A. E. Campbell, Ruth Lemon, G. Blackall, W. L. Duncan, R. H. Micks, R. S. M'Elroy, and Iris P. Nelis.

Part II.

Sanitary Engineering; Practical Sanitary Report; Hygiene and Epidemiology; Vital Statistics and Public Health Law.—A. Darlington, W. L. Duncan, and G. Backall.

Final Dental Examination (B.Dent.Sc.).

J. F. F. Liddy.

Dental Appointments in the Navy.—The following candidates were successful in the competitive examination recently held in London for appointment as dental officers in His Majesty's Royal Navy (their names have been placed in the order of merit shown at the examination):—

O. J. Barrable, L.D.S., Royal Dental Hosp., London; E. R. Longhurst, L.D.S., London Hosp. Dental School; H. N. V. Barnes, L.D.S., Univ. of Bristol Dental School; D. H. le Marchant, L.D.S., Univ. of Manchester Dental School; and D. L. Simpson, L.D.S., National Dental Hosp. of London.

Ministry of Health and the British Empire Exhibition.—The Ministry has prepared a number of exhibits which should prove extremely interesting and instructive to local authorities and their officers. These exhibits, consisting of photographs, plans, models, and the like, will be found in the Government Pavilion and in an annexe, and will be arranged under the following heads: Housing, Town Planning, Disease Prevention, Maternity and Child Welfare, Water Supply, Sewerage and Sewage Disposal, Public Cleansing, Smoke Prevention, and the Welfare of the Blind.

Royal College of Physicians of London.—An extraordinary Comitia of the College was held on March 26th, Sir Humphry Rolleston, the President, being in the chair. The President announced that he had appointed Dr. S. Monckton Copeman as delegate at the Congress to be held by the Royal Sanitary Institute in July next. Regarding certain proposals made to the College by Sir Howard Frank for the transfer of the present site of the College to the Canadian Government, it was resolved "that the College regrets that it is unable to accede to the proposals made by Sir Howard Frank." The question of sending a representative to the General Council of the Fellowship of Medicine was discussed, and on the recommendation of the Censors' Board it was resolved to ask Lord Dawson to act in this capacity.

Fellowship of Medicine and Post-Graduate Medical Association.—During the second week of the fortnight's intensive course at the London Temperance Hospital, which begins on Monday, April 7th, apart from the practical demonstrations, ward rounds, and out-patient clinics, there will be a daily lecture at 4.30 P.M., open to the medical profession. These lectures are: The Diagnosis of the Acute Abdomen, by Mr. V. Z. Cope; On Ophthalmology for General Practitioners, by Mr. Ernest Clarke; Varieties of Dyspepsia and their Differential Diagnosis, by Dr. Soltau Fenwick; Gastro-enterology, by Dr. David Somerville; and the Diagnosis and Treatment of Rectal Cancer, by Mr. W. E. Miles. As part of the course there will be a demonstration on fevers by Dr. Goodall, at the North-Western Fever Hospital, one on Mental Diseases, by Dr. Porter Phillips at the Bethlem Royal Hospital, and an ophthalmological demonstration at the Royal Westminster Ophthalmic Hospital. The fee for the week's course is £2 2*s*. During the week there will be continued the course in ophthalmology at the Royal Westminster Ophthalmic Hospital, consisting of clinical instruction every afternoon from 2 P.M., and special demonstrations in medical ophthalmology and methods of examination on Tuesdays and Thursdays. The following courses will be held in May: A two weeks' intensive course at the Prince of Wales's General Hospital, Tottenham, May 19th to 31st; special courses in diseases of children at the Infants Hospital, May 12th to 24th; diseases of the ear, nose, and throat at the Central London Throat, Nose, and Ear Hospital, May 12th to 30th; proctology at St. Mark's Hospital, May 5th to 17th; psychological medicine at Maudsley Hospital, May 5th to 30th; and venereal disease at the London Lock Hospital, May 5th to 31st. Copies of each syllabus, with full particulars of the above courses, can be obtained on application to the Secretary to the Fellowship of Medicine at No. 1, Wimpole-street, W. 1.

Royal Sanitary Institute.—A sessional meeting will be held on April 11th and 12th in the Council Chamber, town-hall, Newport (Mon.), Dr. Charles Porter presiding. On April 11th, at 2.30 P.M., visits will be paid to the X ray and out-patients' departments of the Royal Gwent Hospital and to the Newport Alexandra Docks. At 4 P.M., at the town-hall, an exhibition of work done by members of the local maternity and child welfare centres will be shown. At 5.15 P.M. discussions will be held on Some Aspects of Child Welfare Work, to be opened by Dr. Minna A. Benner, and on the Increase in the Use of Boric Acid in the Sophistication of Foods, to be opened by Dr. J. Howard Jones. Dr. Ralph M. F. Picken, Dr. J. S. Peebles, Dr. Herbert Jones, and Mr. George Hogan will take part. On April 12th, at 10.30 A.M., visits will be paid to the new works of the Whitehead Iron and Steel Co., Ltd., and to the Newport Gasworks, and special educational films will be shown. At 12 noon, at the town-hall, discussions will be held on Food Hygiene, opened by Mr. Spencer E. Jones, and on Pure Milk, opened by Mr. W. E. Thorn.

Congress of the Royal Sanitary Institute at Bordeaux.—The 1924 Congress of the Royal Sanitary Institute, to be held at Bordeaux under the patronage of the President of the French Republic and the presidency of Viscount Burnham, will be opened on June 4th. The sections of the Congress will be as follows: (1) State Medicine and Municipal Hygiene: Presidents, Sir Humphry Rolleston, Prof. C. Achard; hon. secretaries, Dr. W. Hanna, Dr. J. M. Clements, Dr. R. Pierret. (2) Naval, Military, and Air: Presidents, Surgeon Vice-Admiral Joseph Chambers, Médecin Inspecteur Général Vincent, Dr. Girard; hon. secretaries, Surg.-Comdr. S. Bradbury, Squadron-Leader J. H. Peek, Médecin Major J. Petit, Dr. G. Larrazet. (3) Industrial Hygiene: Presidents, Sir Thomas Oliver, Prof. W. Dubreuilh; hon. secretaries, Dr. G. Hurrell, Dr. C. S. Thompson, Mr. M. D. Wallace. (4) Tropical Diseases: Presidents, Sir Ronald Ross, Prof. A. Calmette; hon. secretaries, Dr. J. G. Thomson, Dr. D. Thomson, Dr. L. Dax. (5) Pathology, Bacteriology, and Biochemistry: Presidents, Sir John Bland-Sutton, Prof. G. Mouriquand; hon. secretaries, Dr. F. Goodwin Rawlinsons, Dr. Arthur Compton, Mr. R. Keith Cannan, Dr. Jeanneney. (6) Women and Public Health: Presidents, H.E. the Marchioness of Crewe, Lady Bland-Sutton (deputy), Mme. Wallerstein; hon. secretaries, Mrs. Alfred Webb-Johnson, Dr. Violet Kelynack, Mme. J. Forsans. The hon. secretaries of the Congress are Prof. E. W. Hope, Prof. R. Cruchet, Dr. T. N. Kelynack, and Mr. E. G. Faure. The central office for registration, information, &c., will be in the Faculty of Medicine of the University of Bordeaux, Place de la Victoire. The London offices of the Congress are at 37, Russell-square, W.C. 1. Specially reduced railway fares (return tickets) have been arranged for members attending the Congress by all routes to Paris and Bordeaux, available from May 31st on presentation of certificate from the Secretary. Membership fee, £1 1*s*.

Hunterian Society.—The annual general meeting will be held on April 7th, at 5.30 P.M., at 94, Harley-street, London, W.

Harveian Society of London.—An ordinary meeting will be held in the Paddington Town Hall on April 10th, at 8.30 P.M., when Sir William Willcox will open a discussion on Insulin.

West Kent Medico-Chirurgical Society.—A meeting will be held at the Miller General Hospital, Greenwich, on April 11th, at 8.45 P.M., when Mr. Percival P. Cole will deliver an address entitled the Surgery of the Face and Jaws.

A Chadwick public lecture will be given at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1, by Dr. Charles Porter, on American Public Health from an English Point of View, on April 8th, at 5.15 P.M.

Diploma in Public Health: Instruction in Hospital Administration.—A three months' course of lectures and demonstrations in hospital administration will be given at the North-Western Hospital, Lawn-road, Hampstead, N.W., by Dr. E. W. Goodall, medical superintendent, on Mondays and Thursdays at 4.30 P.M., and alternate Saturday at 10.30 A.M., beginning on April 3rd.

A meeting of Fellows of the Royal Society of Medicine, Sir William Hale-White presiding, will be held at 1, Wimpole-street, London, W., on April 10th, at 5 P.M., to meet the foreign medical officers of health now in this country, and to hear a lecture communicated by Dr. L. Rajchman, Director of the Health Section of the League of Nations, on the Health Organisation of the League. A preliminary address will be given by Mr. John Wheatley, Minister of Health.

Foreign Decorations.—The King has granted permission to wear the Order of El Nahad which has been conferred by the King of the Hedjaz in recognition of valuable services rendered: Dr. W. Dunlop, director of the Royal Hospital, Baghdad; Mr. G. N. Braham, surgeon, Royal Hospital, Baghdad; and Dr. H. C. Sinderson, railway medical officer, Baghdad (Third Class); and Dr. E. A. Mills, chief pathologist, Baghdad (Fourth Class).

Liverpool Child Welfare Association.—The annual meeting was held on March 24th, when the Minister of Health, Mr. John Wheatley, addressed a large gathering in the town-hall. After paying a well-merited tribute to the fame of Miss Beavan, the chairman of the Association, Mr. Wheatley spoke of the spread of education in health matters as being the most valuable part of the work being done. He was delighted to find that the trend of their activities was more and more in the direction of prevention, and in that connexion stressed the immense importance of proper housing. The ideal, he said, was that the whole nation should be one vast child welfare association, showing the same capacity for idealism and sacrifice as the organisation under Miss Beavan's control.

Donations and Bequests.—By the will of the late Mr. William Hirst Shaw, of Bradford, the testator left, among other bequests, £500 to the Bradford Royal Infirmary and £200 to the Bradford Children's Hospital.—The late Mr. Sydney Wynn Graystone, J.P., of Knightsbridge, left on the decease of his wife and brother large bequests to Downing College, Cambridge, for scholarships and other purposes. He also left £100 to Addenbrooke's Hospital.—Under the will of the late Miss Louisa Rogers, of Shrewsbury, the testator left, among other bequests, £1000 to the Royal Salop Infirmary; £500 to the Eye, Ear, and Throat Hospital, Shrewsbury; £250 to the Shrewsbury Dispensary; and £250 to St. Dunstan's Hostel.—The Chelsea Hospital for Women has received for its new nurses' home £200 from Lord Glendyne in connexion with the fund being raised at the Mansion House.

ASHFORD COTTAGE HOSPITAL.—The fifty-fourth annual report of this institution states that 689 patients were admitted during the year 1923, and 424 operations were performed. These figures show an increase over the previous year, when 613 patients were admitted and 391 operations performed. The daily cost per bed has increased also from 6*s.* 3½*d.* to 6*s.* 8¼*d.* The new apparatus installed in the X ray department in February, 1923, at a cost of £315, has been entirely satisfactory; the work done in this department was nearly double that done in 1922. The number of cases submitted for examination is 264, and 17 underwent treatment. The numbers in 1922 were 162 for examination and 9 for treatment. Mr. Ernest Colville, senior surgeon of the hospital, has been presented by the chairman, on behalf of the committee, with a gold wrist-watch on his retirement from the hospital staff after 38 years' service. It was stated that it would shortly be necessary to increase the capacity of the hospital. Plans had been prepared for double the number of beds now existing, and the cost of the completed work would be from £10,000 to £12,000; but the plans had been laid out in two or three sections. An anonymous offer of £1200 having been received, it was decided to proceed with the first section forthwith, and to build a new ward for six beds, with service kitchen, bathroom and lavatories, a nurses' sitting-room, new kitchens, scullery and larder, a storage room, and a new mortuary. The total cost of these additions would be about £3600.

LIVERPOOL MEDICAL INSTITUTION.—A pathological meeting was held on March 20th, Mr. R. Craig Dun, the senior vice-president, being in the chair. After the exhibition of specimens, which included a unique series of experimental lesions in animals which at least closely resembled those of foot-and-mouth disease, a short discussion took place. Prof. J. M. Beattie gave a brief account of the experimental work done with material obtained from supposed healthy contacts of cases of foot-and-mouth disease and alluded to the almost insuperable difficulties which had been put in his way. In reference to a specimen of epithelioma of the vulva removed with the glands in the groin en bloc by Mr. St. G. Wilson, Prof. Blair Bell spoke of his experience of this operation which had given him uniform success during the last 15 years. Dr. Henry Cohen read a paper on Observations on the Cerebro-spinal Fluid. He reviewed the work of Dandy, Weed, and others on the formation, circulation, and absorption of cerebro-spinal fluid, and gave a brief account of his own work on this subject.

The Relation of Leprosy to Tuberculosis.—A special meeting of medical men of the Liverpool district was held under the auspices of the Liverpool Medical Institution on March 19th, to hear an address by Sir Leonard Rogers on the Problems of Leprosy Research and Their Relation to Tuberculosis. The speaker began by attempting to estimate the number of lepers in the world, assigning at least 500,000 to the British Empire. The size of the problem thus indicated, he proceeded to suggest possible factors in the ætiology of leprosy. Most stress was laid on close contact, especially in warm, moist climates. Sir Leonard Rogers showed maps and statistics with reference to the question of contagion. Although none could claim a high degree of contagiousness for this disease, it was clear that where it did occur it was the result of close contact with actual sufferers. Sir Leonard Rogers proceeded to discuss preventive methods, and described the segregation treatment of the Middle Ages and its effectiveness. The difficulty, he pointed out, was in finding and isolating the early cases, who in Norway, it was estimated, were infective for three years on an average before isolation was carried out. In this connexion the increased susceptibility of young persons was stressed. Modern methods included the abolition of prison-like buildings, the provision of useful work whereby lepers could be made self-supporting, and, above all, improved methods of treatment. He spoke of his attempts to deal with tuberculosis on analogous lines owing to the morphological similarity of the bacillus, and of how this had led him to the introduction of sodium morrhuate in leprosy. This substance, along with ethyl morrhuate, was proving effective in treatment and was much simpler to administer. In conclusion, a series of lantern slides was shown demonstrating the striking results of treatment.

THE LANCET: SUBSCRIPTION RATES.

		£	s.	d.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, MARCH 25TH.

Payments to Insurance Practitioners.

Mr. **FREDERICK GOULD** asked the Minister of Health what was the amount of capitation fee now to be paid to panel doctors per panel person; what was the increase, if any, agreed upon; and from what fund would this money be drawn.—Mr. **WHEATLEY** replied: Payments to insurance practitioners for the current year in respect of medical treatment given to insured persons will be based upon a capitation fee at the rate of 9*s.* per annum in respect of each person entitled to medical benefit. The corresponding capitation fee for the years 1922 and 1923 was 9*s.* 6*d.*

WEDNESDAY, MARCH 26TH.

Patients in Venereal Disease Clinics.

Mr. **SOMERVILLE HASTINGS** asked the Minister of Health the percentage of patients treated in the venereal disease clinics during the last year under the age of 18 and 20 years. —Mr. **WHEATLEY** replied: Figures are only available for the first three months of 1923. During that period 6·4 per cent. of the total number of patients attending the treatment centres for venereal diseases for the first time and found to be suffering from these diseases were under 18 years of age, and 7·8 per cent. were under 19 years of age. Figures are not available as regards the number of patients under 20 years of age.

Extension of Insurance Medical Benefit.

Mr. **PALMER** asked the Minister of Health if he would consider the need for medical benefit to be extended to members of approved societies whose service conditions entitled them to a pension at the age of 60 years, and thereby took them out of employment and the provisions of the National Health Insurance Act.—Mr. **WHEATLEY** replied: The hon. Member's suggestion would require legislation, and the matter is one which will, no doubt, be considered by the Royal Commission.

THURSDAY, MARCH 27TH.

Re-assessment by Medical Boards.

Lieut.-Colonel **ASSHETON POWNALL** asked the Minister of Pensions the result of the medical boards held for purposes of re-assessment during the last six months of 1923, showing the percentage of pensions increased, decreased, and unchanged, and the net result.—Mr. **F. V. ROBERTS** replied: During the period referred to 190,000 cases came up for medical re-examination by boards. As a result of this review, in 55 per cent. of the cases pension was renewed at the previous rate; in 21 per cent. of the cases the pension rate was increased; and in 24 per cent. it was reduced. The net result of these changes was a net increase of 0·6 per cent. in the average rate of disablement.

Mental Patients in Prisons.

Major Sir **ARCHIBALD SINCLAIR** asked the Home Secretary whether his attention had been called to the statement in the report of the Prison Commissioners for the year ending March 31st, 1923, with regard to the presence in prison of a class of prisoners who, on account of mental retardation or mental instability, or both, are incapable of profiting by training and discipline, and to a statement by the Commissioners that there was a need for a special form of curative treatment under a specially trained staff in an environment other than that of a prison for these persons; and whether he proposed to take any steps to give effect to this recommendation.—Mr. **HENDERSON** replied: A scheme is now being prepared by the Commissioners to collect unstable mental cases, not certifiable under the Lunacy or Mental Deficiency Acts, and sentenced to imprisonment long enough to justify transfer, in certain selected centres and to place them under the tuition of a specially trained staff and close medical observation.

Child Assault Cases.

Lieut.-Colonel **RUDKIN** asked the Home Secretary whether his attention had been called to the increasingly numerous cases of child assault; and whether he would consider the advisability of appointing a committee, including medical and legal experts, to inquire into these matters and the ratio of convictions obtained in the cases known to the police, the best means of preventing these offences and of dealing with the offenders, and as to the adequacy of the provisions made to protect children and the provision made for the unfortunate victims.—Mr. **Henderson** replied: Yes, Sir, as indicated in my reply on March 6th, a conference has been held at the Home Office when this matter was fully discussed. I am now considering the appointment of a suitable committee for investigation and report. I may add that there is no evidence of any increase in the number of these offences over a period of 25 years.

Tuberculous Persons in Milk Trade.

Mr. **John Harris** asked the Minister of Health whether he would consider the desirability of obtaining powers for local authorities administering tuberculosis regulations to take steps to prevent persons suffering from infectious tuberculosis from dealing directly with the distribution and sale of milk.—Mr. **Wheatley** replied: Yes, Sir.

Special Hospitals for Early Mental Cases.

Mr. **Costello** asked the Minister of Health whether, with a view to providing facilities for the recovery of early mental cases which could not be proved to be dangerous or unfit to be at large, he would take steps to enable and encourage, by means of national grants, the establishment of appropriate hospitals under the management of the health committees, as distinct from the asylums committees, of local authorities. —Mr. **Wheatley** replied: The point raised by the hon. Member will receive the consideration of the Government.

Expenditure of the General Nursing Council.

Mr. **Herbert Morrison** asked the Minister of Health whether he had received from the National Asylum Workers' Union a resolution protesting against the expenditure of the General Nursing Council and asking that the fees charged by the Council should be reduced; and what action he proposed to take in the matter.—Mr. **Wheatley** replied: The resolution to which the hon. Member refers cannot be traced, but I am not prepared to express any opinion on this question until I have received definite proposals from the General Nursing Council as to the scale of registration and examination fees necessary, in their opinion, to make the Council self-supporting.

Lunacy Certification.

Mr. **Rawlinson** asked the Prime Minister whether his attention had been called to the fact that, in the process of certification of an alleged lunatic as ordinarily conducted, the magistrate only heard evidence against the sanity of the individual; and whether he would bring in legislation enabling the alleged lunatic to have the opportunity, if he desired it, of having his case placed before the magistrate by his legal adviser, who should be entitled to test the adverse evidence by cross-examination and, if necessary, to call rebutting evidence.—Mr. **MacDonald** replied: The points raised will no doubt be considered by any Commission that may be appointed to inquire into the Lunacy Laws, and I cannot give any undertaking to introduce legislation in anticipation of such an inquiry.

Monday, March 31st.

Panel Practitioners' Fees.

Mr. **Wheatley**, the Minister of Health, in moving the second reading of the National Health Insurance (Cost of Medical Benefit) Bill, said that the object of the Bill was to provide money to meet the balance of the cost of medical benefit and administration beyond the sum provided for by Section 7 of the Act of 1920. Under that Act the Minister of Health was empowered only to authorise the payment to the doctors of about 7*s.* 3*d.* per head per annum of the insured persons. The Court of Inquiry reported in January in favour of 9*s.* per head, and the Bill provided for the payment of this amount. By the arrangement which he had come to with the approved societies the money was to be found without any grant being required from the Exchequer and without any of the accrued surpluses of the approved societies which were available for additional benefits being earmarked for this purpose. The Bill was for three years. It was hoped that within that time the Royal Commission which he proposed to set up would have reported, and that legislative effect would have been given to its recommendations. The total amount required to tide over the three years, including the statutory allowance of two-ninths from the Treasury, was £1,762,000. The sum to be found for England, Scotland, and Wales respectively varied somewhat because of the differences in the cost of administration in the three countries. The sum required for England was 2*s.* 4½*d.* per head per annum. It was proposed to obtain the money from three sources—first, 2*d.* out of the funds of the approved societies, which they offered because they felt that they were entitled to pay something for the services of regional medical officers who acted as referees, and for the keeping of a central index of insured persons. In order to strengthen the Central Fund for the immediate purpose of the Bill it was proposed to make a special grant of £100,000 from the reserve and to make it from the unclaimed stamps account. The Central Fund being thus further strengthened would be in a position to give them 1*s.* 8½*d.* per head per annum without impairing its efficiency for its main purpose. The approved societies had always large sums of money in the hands of the National Loan Commissioners, held under a guaranteed rate of interest. If the Commissioners obtained more than 4½ per cent., then the excess was credited to a reserve account that went to the benefit of the society. The fund at the moment was in a position to give them 6*d.* per head per annum for the next three years, and the societies had agreed that that should be taken. Clause 2 provided for the transfer of the £100,000 to the Central Fund. Clause 3 re-enacted the provision in the Act of 1922, which enabled societies to provide benefits to members who would otherwise not receive benefits because of prolonged unemployment. Clause 4 extended the Act to Northern Ireland, and Clause 5 applied it to Scotland and Wales. Clause 4 made the Act retrospective to Jan. 1st of this year. The Bill was one on which there was general agreement among all parties concerned.

In the discussion which followed Sir **Kingsley Wood** said he regretted that the Government had not been able to announce the terms of reference to the Royal Commission. It was very important that those terms should be full and ample enough to cover every phase of national insurance to-day. While he believed that the great majority of the medical profession were endeavouring loyally to carry out their contracts, that could not be said of every one of them. He was very glad an important alteration had been made, and that every person who wanted to change his panel doctor could do so immediately by simply taking his card to another doctor on the panel. They would not get an efficient medical service and proper value for the money now being paid while they retained the large panel lists. The present number of 2500 persons on one doctor's panel was far too many.

Dr. **Chapple** contended that if they introduced into the approved societies a wealthy class of member they would make a greater demand on the practitioner, and that was why the practitioners, who were at one time content with a lesser sum, now found that 9*s.* was not enough.

Lieut.-Colonel **Fremantle**, in supporting the second reading, pointed out that the medical profession had not made any undue demand in the terms for which they had stood out. Dealing with the suggestion that the right of the patient to change his panel practitioner was due to the demand of the approved societies, he said that the demand came not from the societies but from the Insurance Acts Committee of the British Medical Association. The latter body had always been keen on absolute freedom of choice both by practitioners and by patients. It was to the committee's credit that they should have demanded this freedom, and he was glad it had been granted. They had also demanded the Commission, and they recognised it was part of a larger series of questions. As to pledges, he said that the one demanded of him by the approved societies was absolutely unjustified. He was not in a position to give the pledge, because he was not in a position to judge of the questions at the time. But the societies demanded the pledges in such a manner that many candidates might well have been afraid to refuse. He was able to refuse, and, as a result, his majority at the election was increased.

The second reading was agreed to without a division.

Tuesday, April 1st.

Imported Chilled Meat.

Viscount **Curzon** asked the President of the Board of Trade if he would state what quantity of chilled meat, acted upon by formaldehyde as a preservative, was being imported into this country by the s.s. *Kent*, or any other ship; if the medical officer of health at the port where this experimental consignment arrives was satisfied that the meat thus preserved with formaldehyde was fit for human consumption; was the meat on this pronouncement to be placed on the market; and what would be the functions in this matter of the departmental committee which was now sitting.—Mr. **Wheatley**, who replied, said: I am informed that the quantity of chilled meat being imported in the s.s. *Kent* is 463 quarters, and I am not aware that any arrangements have been made for further consignments of meat treated by formaldehyde. If the port medical officer of health is satisfied after examination of the consignment that the meat is fit for human consumption it will, no doubt, be placed on the market in the usual way. I understand that the departmental committee on preservatives in food propose to arrange for the inspection of the meat and investigation of the process for the general purposes of their inquiry.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, April 8th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.
Annual General Meeting:
Election of Officers and Council for 1924–25.
Papers:
Dr. Symes-Thompson: The Occurrence of Symptoms following the Simultaneous Use of Adrenaline and Cocaine.
Dr. P. Hamill: The Use of Atropine in Conjunction with Digitalis.
Dr. E. Cowles Andrus: The Clinical Administration of Digitalis in the Form of Powdered Leaf.

Thursday, April 10th.

SPECIAL MEETING OF FELLOWS: at 5 P.M.
To meet the Foreign Medical Officers of Health now in this country, and to receive a communication from Dr. Rajchman (Director of the Health Section of the League of Nations) on the Health Organisation of the League.
A preliminary address will be given by The Right Hon. John Wheatley, M.P., Minister of Health.
Tea and coffee will be served at 4.30 P.M.

NEUROLOGY: at 8.30 P.M.
Discussion:
On the Value of X Rays in the Localisation of Cerebral and Spinal Tumours, with Special Reference to Ventriculography and Lipiodol Injections, to be opened by Mr. Percy Sargent and Mr. Geoffrey Jefferson.

Friday, April 11th.

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
Cases:
Dr. Hildred Carlill: (1) Pathological Laughter in a Woman of 66 with High Blood Pressure; (2) Lightning Pains of Tabes Dorsalis persisting in (inter alia) a Limb which was Amputated in 1910.
Dr. Douglas Firth: Juvenile Myxœdema.
Other cases will be shown.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
Tuesday, April 8th.—5 P.M., Dr. Thomas McCrae: Clinical Features of Foreign Bodies in the Bronchi. (Second Lumleian Lecture.)
Thursday.—5 P.M. (Last Lumleian Lecture.)

SOCIETY FOR THE STUDY OF INEBRIETY, 11, Chandos-street, London, W.
Tuesday, April 8th.—4 P.M., Dr. Bedford Pierce opens a discussion on Mental States in Alcoholism.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
Monday, April 7th.—10 A.M., Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M., Mr. Simmonds: Surgical Out-patients.
Tuesday.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
Wednesday.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Skin Department. 2.30 P.M., Mr. Armour: Surgical Wards.
Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Department. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
Friday.—11 A.M., Dr. McDougal: Electrical Department. 12 noon, Mr. Endean: Venereal Diseases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Department.
Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily 10 A.M. to 6 P.M., Saturdays, 10 A.M., to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE. (Prince of Wales's General Hospital.) (At 4.30 P.M.)
Monday, April 7th.—Dr. S. Cochrane Shanks: X Ray Appearances of Tumours of Bones.
Tuesday.—Dr. F. G. Crookshank: Thyroidal Deficiencies.
Wednesday.—Mr. Norman B. B. Fleming: Iritis.
Thursday.—Mr. H. W. Carson: Diagnosis of Cancer of the Rectum.
Friday.—Dr. L. R. Yealland: Clinical Demonstration of Cases.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.
Thursday, April 10th.—4 P.M., Mr. Addison: Hæmaturia. Pyuria.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
Thursday, April 10th.—5 P.M., Mr. Davies: Abortion.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
Tuesday, April 8th.—4.15 P.M., Dr. E. M. Brockbank: Thoracic Pain.

MANCHESTER BABIES' HOSPITAL POST-GRADUATE LECTURES.
Friday, April 11th.—5.30 P.M., Dr. Chisholm: Complications met with in the Treatment of Marasmic Infants.

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal Mineral Water Hospital.—P.
Bethlem Hospital, Lambeth-road, S.E.—Two Res. H.P.'s. Each £25 per quarter.
Birmingham, St. Chad's Hospital.—Res. M.O. £100.
Bournemouth, Royal Victoria and West Hants Hospital.—Asst. Hon. Bacteriologist, &c.
British Guiana Diamond Fields.—Government M.O. £500.
Charing Cross Hospital, W.C.—Med. Reg. and Surg. Reg. Each £150. Also Asst. Surg.
Derbyshire Royal Infirmary, Derby.—H.S., &c. Also Asst. H.S., &c. Each £200.
Dublin University, Trinity College.—Prof. of Pathology. £800.
East London Hospital for Children, &c., Shadwell, E.—H.P. £125. Also Afternoon Cas. O. £120.
Gold Coast, Takoradi Harbour Construction Works.—M.O. £1000.
Herefordshire General Hospital.—H.P. £200.
Hospital for Consumption and Diseases of the Chest, S.W.—H.P. £50.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—H.P. £100. Also Asst. P.
Kensington, Fulham, and Chelsea Hospital, Richmond-road, Earl's Court, S.W.—Sen. and Jun. Res. M.O.'s. £100 and £75 respectively.
Leeds University, Dept. of Pathology and Bacteriology.—Lecturer in Pathology. £500.
Manchester, Baguley Sanatorium.—Third Asst. M.O. £400.
Manchester, Royal Manchester Children's Hospital.—Asst. M.O. £150.
Metropolitan Hospital, Kingsland-road, E.—Sen. H.P., H.S., Jun. H.P., H.S., and Two Cas. O.'s. Each £100. Hon. Anæsthetist.
Middlesex Hospital Medical School, W.—Asst. to Prof. of Experimental Path. £350.
Northampton General Hospital.—Hon. P.
Pontefract, General Infirmary and Dispensary.—Res. Surg. O. £400.
Rainhill, County Mental Hospital.—Asst. M.O. £300.
Royal College of Surgeons of England.—Examiners.
Royal Northern Hospital, Holloway, N.—H.P. and H.S. £75.
Somerset Mental Hospital, Wells.—Asst. M.O. £300.
Southampton Free Eye Hospital.—Locum Tenens Ophth. H.S.
Stafford, Coton Hill Mental Hospital.—Med. Supt. £600.
Throat Hospital, Golden-square, W.—Hon. Surg. Reg.
Tunbridge Wells General Hospital.—H.S. £160.
Union of South Africa Government Mental Hospital Service.—Asst. P.'s. £460.
West End Hospital for Nervous Diseases, 73, Welbeck-street, W.—Cas. P. £200.
West London Hospital, Hammersmith-road, W.—Hon. Med. Reg.
Willesden General Hospital, Harlesden-road, N.W.—H.S. £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Kidwelly, Carmarthen; Levenwick, Shetland; Scalloway, Shetland.

Births, Marriages, and Deaths.

BIRTHS.

Coope.—On March 26th, to Rosalind, the wife of Robert Coope, M.D., M.R.C.P., of 28, Rodney-street, Liverpool, a daughter.

MARRIAGES.

Langwill—Judd.—On March 22nd, at the Church of St. Martin-in-the-Fields, Archibald Langwill, M.D., F.R.C.S.E., to Marguerite Ethel, elder daughter of Henry Kerridge Judd, of Edgware.

DEATHS.

Claremont.—On March 27th, of typhoid and broncho-pneumonia, Ethelberta Claremont, M.B., M.S. Lond., F.R.C.S. Eng., aged 31.

Eccles.—On March 24th, at "Nafferton," Broadhurst-gardens, Hampstead, Dr. Charles Henry Eccles, aged 58 years.

Johnston.—On March 25th, at Princes-square, W., James Johnston, M.D., F.R.C.S. Edin., formerly of Shanghai, in his 86th year.

MacBride.—On March 18th, at 74, Rodney-street, Liverpool, Mary Monica MacBride, Sister on the Staff of the Royal Infirmary, Liverpool, from 1880 to 1905, aged 69 years.

MacCulloch.—On March 26th, at The Bury, Branksome Park, Bournemouth, William Mansell MacCulloch, M.D. Edin., at one time Jurat of the Court of Guernsey, aged 75.

Taylor.—On March 29th, at Weoley-hill, Birmingham, E. Claude Taylor, M.D., M.S., F.R.C.S., formerly of Hampstead, aged 53.

Williams.—On March 24th, at Bronheulog, Burry Port, Owen Williams, J.P., L.R.C.P., L.R.C.S., aged 70.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

CANADA'S LITTLE BLUE BOOKS.

"The Canadian Mother's Book" was first published in 1921, and offered free to any mother who cared to apply for it. By 1923 more than 220,000 copies had been supplied, largely in response to individual requests. The mothers themselves christened the pamphlet "the little blue book," and, encouraged by the eager demand for it, the Canadian Department of Health proceeded to issue other little blue books. There are now three different groups—the Mother's Series, the Home Series, and the Household Series—each containing five pamphlets. The whole 15 are the work of Dr. Helen MacMurchy, chief of the Division of Child Welfare; and anybody who has been tempted to feel that all there is to say about child welfare has already been said will thank the author for her freshness and vitality both of thought and expression.

The first series is perhaps the most generally useful, since the fundamental needs of mothers, fathers, and children are much the same in all countries. Dr. MacMurchy sets a high standard, and believes the best of her average family, assuming as a matter of course that each member will be anxious to take his or her share in the home-making as soon as it is understood. She utters wise warning against what is perhaps the commonest mistake of an unselfish mother—allowing herself to become a perfect drudge, and spoiling the family at the same time.

> "Teach your children to help you and to help themselves. Don't do anything for them that they can do for themselves.
>
> The division of labour is a great principle in the home. 'Company manners' are the worst manners in the world. Good home manners are the only kind worth having—they never wear out."

Dr. MacMurchy sets great store upon the mother's preservation of her individuality, her tastes and interests, and advises her, at all costs, to arrange things so that she does not work the whole of any day. Only in this way can she possess herself, and preserve the spirit of serenity which goes so far to produce a happy home.

When Dr. MacMurchy refers directly to questions of children's health, her remarks are precise and very much to the point. For example:

> Sore eyes in a little baby are very dangerous. Get the doctor this minute.
>
> It is wrong to subject children at the formative period of life, when impressions are so deep and lasting, to the shock and pain of contact with mental illness.
>
> Children can't hurry. Their reaction time is longer than ours. Parents and teachers who talk about "instant obedience," please take notice. Instant obedience in you is about ten times faster than in a child.

While endorsing what is said about the high value of milk as a food for children, the injunction that *all* milk should be pasteurised would be regarded here as a little sweeping. It is useful to be reminded once again that milk is a solid food about one minute after it has been swallowed, so that it should be taken slowly.

There are many excellent hints in the Home Series and Household Series, including advice as to such matters as posture and avoidance of unnecessary fatigue, but these pamphlets are of rather less universal application than those in the Mother's Series. In reading them an impression is received of wide spaces, open-air conditions, and a general atmosphere of elbow-room, which is unfortunately far from familiar to poorer housewives in this country. An agreeable sense of surprise is also conveyed by the long list of Government departments and voluntary agencies to which the mother is invited to write for any help or advice she may require, being assured of their pleasure in hearing from her and their desire to be of service.

"RECOMMENDED BY THE PORTER."

The ideal head-porter at the large hotel is presumed by the public to be able as well as willing to supply information to the visitor on any topic under the sun. And there must be few of us who have not cause to remember with gratitude the practical help which we have received from these energetic and adaptable polyglots. But while the advice is valuable on such subjects as the selection of suitable shops for our purchases, and of suitable routes for our future journeys, as on passport and currency difficulties, the head-porter's opinion on the relative merits of the available medical practitioners has to be received with caution. The traveller should hesitate, we feel, to accept the porter's recommendation of a medical man in preference to the hotel doctor. The latter practitioner has been chosen by the management for good reasons, in which the reputation of the establishment plays its part; the selection of the porter may have a different bias. But the situation is not always as simple as this. A complaint reaches us, for example, from a hotel doctor in Bombay, stating that a notice had been placed in a telephone box of the hotel giving detailed information as to where another medical practitioner was to be found at various times of the day. Our correspondent comments unfavourably on the professional position displayed, because he believes that the medical man in question either is prevented or should be prevented by his official position from competition in private practice. That is a matter which could easily be settled, we suppose, by submitting a question to the proper authority, but it is clear that this is not a case of "Recommended by the porter." The hotel management has the control of its own telephone boxes, and must have sanctioned or approved the appearance of the notices.

"MOTHERCRAFT."

We have received from the National League for Health Maternity and Child Welfare (Carnegie House, 117, Piccadilly, London, W. 1) a copy of the fourth edition of a popular manual on "Mothercraft." This is a selection from courses of lectures on infant care, delivered under the auspices of the National Association for the Prevention of Infant Mortality. The book has been revised, new chapters having been added on the Nervous Child by Sir Maurice Craig, the Backward Child by Dr. A. F. Tredgold, and Diseases of the Skin in Infancy by Dr. H. G. Adamson. More than 30 separate subjects are dealt with by acknowledged experts, and the book justifies its claim to be a complete and up-to-date work of reference on all that relates to the care of infants and children under five. The price has been reduced from *5s. 6d.* to *4s. 6d.*, post free.

HOSPITALS AND DISPENSARIES IN BURMA.

During the year 1921 the number of patients treated in the 278 hospitals and dispensaries in Burma amounted to 1,885,944, of which 79,858 were in-patients; the daily average of the latter under treatment being 3445. The very great increase in the beneficent work of these institutions is shown by comparison with the figures for 1900, when the total treated numbered 858,689, of whom 36,095 were in-patients. For the province as a whole malaria and its results furnished the largest number of patients (12,761 indoor and 256,776 outdoor); after this, diseases of the eye (1742 indoor and 118,839 outdoor). Venereal diseases caused 7252 admissions to hospital, and in addition 44,792 outdoor patients were treated. Of those admitted to hospital, 4913 were suffering from syphilis, 51 cases terminating fatally; among the 1608 cases of gonorrhœa or its results (rheumatism, ophthalmia, &c.) 18 deaths occurred; in a third category of "diseases of venereal origin—non-infective, i.e., non-syphilitic venereal sore, inflammation of lymphatic glands, salpingitis, pelvic abscess," are included 731 cases, with 8 deaths. The total operations performed numbered 57,181, an increase of 954 on the year preceding. Several new hospitals have been opened, or are under construction, but it is stated that "most of the hospitals throughout the province are of wood, unsuitable, out of date, and many of them in indifferent repair." The report is prefaced by a very interesting résumé of the progress and development of hospital construction in Burma, by Mr. W. B. Brander, Secretary to the Government. The first hospital was established at Akyab in 1826; the first separate report on the hospitals and dispensaries in the province related to the year 1865–66, when there were 13 institutions at work, treating in all 2985 indoor and 19,804 outdoor patients. Sir Reginald Cradock, Lieutenant Governor of Burma, in a Government resolution, records his "sincere appreciation of the services which Lieut.-Colonel Entrican has rendered to the cause of medical science in this province," and "believes that whatever the future may bring forth, the people of Burma have now too high an appreciation of the value of the methods of Western medicine to discard them for the empirical methods and antiquated ideas of systems not based on accurate scientific knowledge."

There are two lunatic asylums in Burma, one at Rangoon, accommodating 632 patients, and the other at Minbu, on the Irrawaddy near the southern border of Upper Burma. In both asylums there was overcrowding during 1921; at Rangoon the daily average inmates numbered 753, the accommodation being planned for 632; and at Minbu the space allowed for each inmate was only 36 square feet. The admissions numbered 209, and in addition there were 21 observation cases; the total number, 230, being a slight increase on the corresponding figure (220) for the previous year. The discharges numbered 138, of whom 87 were "cured." In regard to the general health of the inmates, the report does not enter into particulars; the death-rate was 7·74 per cent. of the average strength, a slight increase on the previous year (6·77 per cent.); at Minbu there were no deaths. Tuberculosis accounted for 21 deaths out of the total 69. As to causation of insanity among the inmates, Colonel Entrican remarks on "the continued increase of cases attributed to drugs, from 23 in 1920 to 33 in 1921." For several years past this increase has been going on steadily.

Lumleian Lectures

ON THE CLINICAL FEATURES OF

FOREIGN BODIES IN THE BRONCHI.

Delivered before the Royal College of Physicians of London

BY THOMAS McCRAE, M.D., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

LECTURE I.

Delivered on April 3rd, 1924.

INTRODUCTION.

THE subject of these lectures is, doubtless, regarded by many as one of the curiosities of medicine, and having but slight practical importance. There are no statistics to show the frequency with which foreign bodies gain entrance to the bronchi, but it is certainly much more common than is generally recognised. The increase in the number of cases recognised in a community, as more attention is directed to the condition, is parallel to the increase in the number of cases of pernicious anæmia in a district which results from better knowledge of the disease. The figures from the Jefferson Hospital are no guide, for patients come to Chevalier Jackson from all parts of the United States and Canada.

The opportunity to study the clinical features of this problem has come through the kindness of my colleague, Prof. Chevalier Jackson, whose work in bronchoscopy stands out as one of the great contributions of American medicine. Only those who have seen his clinic can realise fully the skill of his technique, and the thoroughness and care with which the problems are studied.[1] From the medical side the procedure adopted has been to study the patients without any knowledge of the X ray report, and in many cases without knowing the history, so that the physical findings have to be interpreted without any other information. The object is to determine (1) whether a foreign body is present, (2) where it is situated, and (3) its nature, if possible.

The causes responsible for the entrance of foreign bodies into the air passages are inherent in human nature and are not peculiar to any country. The most important factor in adults and older children is the reprehensible habit of using the mouth as a sort of hold-all for objects such as pins, tacks, nails, &c. The individual is startled, coughs, laughs, speaks, or makes a sudden movement, and with the succeeding inspiration the object passes into the air passages. In small children there is a common tendency to introduce any object, whose size does not forbid, into the mouth, and the possibility of aspiration into the trachea is always present. The factor of imitation is also important. The child sees the mother or nurse putting pins into the mouth, and nothing is more natural than to follow the example. A dentist may permit an extracted tooth, a dental fitting, or a small instrument to fall back into the pharynx whence it may pass into the larynx. (Fig. 1.) Pieces of bone may be aspirated, and in this case hurried eating is usually responsible. Many candies contain nuts, which may be aspirated after the soluble candy is dissolved. In general, we may regard carelessness as the main contributing cause in those who have reached years of discretion. In the cases in which the foreign body gains entrance during anæsthesia the patient is innocent, but there is usually carelessness on the part of someone.

Variety of Objects Inhaled.

The variety of objects, both in size and character, which may gain entrance to the air passages is remarkable. The largest of which I know was an oyster which passed as far as the bifurcation of the trachea, a portion passing into each bronchus and causing complete obstruction, the patient dying quickly. The smallest was a portion of nut aspirated while the patient was chewing. The diverse character of objects is worthy of note. As might be expected, pins are common, both the ordinary variety and safety-pins. (Figs. 2 and 3.) The latter are often aspirated when open, adding to the difficulty of extraction, as the point often penetrates the wall of the trachea or bronchus. Tacks and small nails and screws are comparatively common, the brass-headed variety being especially frequent in small children, whose attention is, no doubt, attracted by the appearance. (Fig. 4.) Small toys and portions of toys are not uncommon. (Fig. 5.) Buttons, beads, and small pieces of jewellery are easily aspirated. Bones may pass into the air passages, especially soft chicken bones. A very important and large group includes nuts, beans, and seeds. (Fig. 6.) In the United States the peanut is a favourite article of consumption—alone or in candy—and either a whole nut or a portion is easily aspirated. The folly of giving nuts to young children who cannot chew them is evident. The form of candy which contains nuts is a frequent source, as after the candy is dissolved the nut remains. A child often eats rapidly and chokes easily, and as this is followed by a deep inspiration the aspiration of a portion of nut readily follows. Grains of corn, various seeds, especially of the water-melon, and pieces of grass and bark are among the objects which gain entrance to the air passages.

The relative frequency of the substances of vegetable origin is shown by the figures of 100 consecutive cases. A peanut, or a portion of one, was found in 45 cases, a grain of corn (maize) in 17, a water-melon seed in 15, and miscellaneous objects in the remainder. This last group includes shells of various nuts, beans, almond nuts, walnuts, coffee-berry, apple-stems, burrs, &c.

The influence of the flora of a district is well demonstrated by H. M. Taylor,[2] of Florida, who reports a number of cases in which the sand spur, which is common in that State, gained entrance to the air passages. This has sharp barbed spines, which usually catch in the larynx.

The determining factors are many. While having an object in the mouth the individual speaks, laughs, coughs, makes a mis-step, or is startled. The next inspiration, which may be an unusually strong one, draws the object into the larynx. The contact of a foreign body excites cough, and the tendency to take a deep inspiration before coughing naturally favours aspiration of the substance. Everyone has experienced the discomfort of having a drop of water or a crumb "go the wrong way." This often occurs without any evident reason. If an object is held in the mouth it may pass into the air passages just as easily. Some of the cases result from various combinations of circumstances. For example, a mother was holding her child, aged 3 months, in her lap when a small open safety-pin insecurely fixed in the mother's dress fell into the child's mouth and passed into the larynx. The pin was removed 36 hours later, the child being none the worse. In another case a man was asked to pin his nephew's collar at the back. He placed the pin in his mouth and the nephew then gave him a sudden blow on the abdomen with his elbow. There was a natural sudden start followed by a deep inspiration and the pin disappeared. It was removed some days later from a bronchus.

As a rule the foreign body travels downward in the air passages as far as possible. In a certain proportion of cases the body remains in the trachea; this may be for a time only or until removed. Permanent lodgment in the trachea may result from the size of the object in some cases, but more often from its shape or from its having a sharp point which becomes fixed in the wall. The object is more likely to enter the right main bronchus than the left, the proportion entering the right side being about 66 per cent.

---

[1] Chevalier Jackson: Surgery, Gynecology, and Obstetrics, March, 1919, pp. 208–268.

[2] Jour. Amer. Med. Assn., 1921, 77, 685.

Dr. Jackson's work has shown that the most frequent site of lodgment is at or just below the giving off of the right upper lobe bronchus and the next most frequent the corresponding spot on the left side. Next come the stem bronchi, the dorsal branches being more often invaded than the ventral branches. The branch most frequently invaded is the large posterior branch of the left lower lobe bronchus which is given off immediately below the upper lobe bronchus.

Symptoms at Time of Aspiration.

A study of the symptoms at the time of aspiration is important, because in many cases the diagnosis is not made because there was no special resulting distress. There may be great variation in the immediate symptoms. If the body remains in the trachea there is usually extreme distress with dyspnœa, decreased if the object passes into a bronchus. A movable body in the trachea usually causes marked distress. An object such as a safety-pin may result in slight symptoms only. In many cases there is considerable distress with choking, strangling, and coughing, which, however, soon lessen. In some cases in adults who knew that the object had passed into the air passages, the statement is made that there was surprisingly slight discomfort. Naturally, the size and character of the object influence markedly the severity of the initial symptoms. Certain cases in adults in which there was no knowledge of even the possibility of a foreign body having gained entrance to the air passages prove that there may not be sufficient symptoms at the time of aspiration to attract attention. Some of the accounts given by the patients are as follows:—

1. A woman was having dental work done, and a small dental instrument was placed in a root canal. She felt it slip out of the tooth and lodge on the tongue. She tried to take hold of it, but it slipped from her fingers into the air passages. She had an attack of severe coughing, but nothing more.

2. A man standing on a ladder and holding a staple an inch long in his mouth was asked a question ; in answering it the staple disappeared. There were no symptoms of any kind at the time. Next day he had a tickling sensation in the throat, which led him to consult a physician.

3. While a dentist was fitting a gold bridge it slipped from his hand and was aspirated. The patient had a momentary sensation of something in the throat, and an attack of coughing much the same as if a drop of fluid had " gone down the wrong way." The lack of any respiratory distress led to the view that the object had been swallowed.

4. A child came into the house and announced that she had swallowed part of a toy. There was such an absence of disturbance of any kind that the parents refused to believe her. The truth of her story was proved seven years later by the removal of the object.

5. A young woman aspirated a safety-pin, which she said " went down as easily as a drink of water."

These cases illustrate how little disturbance there may be from the aspiration of a foreign body. Between them and the cases with a maximum severity of symptoms, as when the body is in the trachea or sets up a severe general tracheo-bronchitis, there is every variation. In many patients after a period of distress and severe cough the main complaint is of cough and dyspnœa, which vary greatly in severity. In young children nothing may be known of the initial symptoms ; the child may be too young to tell or may be frightened and make no mention of the happening.

After the symptoms which occur at the time of aspiration, special importance belongs to the period after the foreign body has gained entrance. The first symptoms may be of short duration and following this there is often a *quiescent interval* in which symptoms are entirely lacking or are so slight that they do not attract attention. This quiescent period has often been responsible for the opinion that it was impossible that a foreign body was in the air passages. This symptomless period is most deceptive, as the initial manifestations, which may be slight or severe, are quite forgotten when later symptoms appear and an association between the two is not recognised. Many such cases might be reported.

Nail in Bronchus.—A boy, aged 14 years, was admitted on Oct. 8th, 1923, without any complaint of symptoms, but a knowledge of having " swallowed " a nail. On Oct. 6th, 1923, he had a nail, from which the head had been removed, in his mouth. He laughed and the nail disappeared. It stuck in his throat for a short time, causing gagging, and then he felt it pass downward. After this he did not have a symptom of any kind. His mother insisted on an X ray study, which showed the nail in the left lower lobe bronchus. The only sign observed was decreased expansion in the lower left thorax.

A boy, aged 6 years, was admitted on Nov. 12th, 1923, complaining of cough and wheezing respiration. About two and a half years before the child became very ill, without any definite cause, and the condition was diagnosed as pleurisy. The mother thought that he had been playing with a nail which disappeared. The child recovered and seemed perfectly well. Some time later the child began to cough, and this gradually became more troublesome. In October, 1923, an X ray plate was taken, which showed the nail in the right lower lobe bronchus. The child showed lack of both physical and mental development, and extreme clubbing of the fingers. The breath had a very foul odour. The signs over the lower right lung were marked and varied from day to day, evidently depending on the relative amounts of air and secretion present. The blocking of the bronchus was not complete. At bronchoscopy (Jackson) a stricture was found in the lower right lobe bronchus, below which was a cavity containing foul pus in which the nail was found.

This period of freedom from symptoms is specially emphasised, as ignorance of its occurrence has so often led to the supposition that a foreign body could not be present owing to the absence of symptoms. In many cases this quiescent period does not occur, and symptoms are constant from the time of aspiration.

Resulting Changes.

It is evident that many factors may influence the changes which result from the presence of the foreign body. Some of these are worthy of discussion.

1. *Age.*—The air passages of infants and young children react much more severely to the irritation of a foreign body than do those of older children and adults. This applies especially to the subglottic region in children below a year and a half of age. Swelling may be excited by many factors, and among foreign bodies the irritation produced by a nut is specially acute.

2. *Trauma.*—This may be direct, as when the foreign body is moved about actively by respiration and cough, especially in the trachea, or by injury from the point of a pin or the edges of a sharp object. Infection of the tissues may result if the mucosa is injured.

3. *Mechanical.*—The foreign body may injure the mucosa to a greater or less extent. In the case of a bean the absorption of moisture may cause it to swell and so increase the pressure. The swelling of the mucous membrane, which results from inflammation, acts in the same way. The interference with the passage of air is discussed subsequently.

4. *Special Forms of Irritation.*—These are seen particularly with nuts, beans, and substances of vegetable origin. A most intense tracheo-bronchitis is set up, which requires special discussion.

5. *Infection.*—This may result quickly or slowly. If very intense, as in the peanut cases, this may kill the patient in a short time. In the more chronic cases there is the formation of foul pus often associated with abscess formation and bronchiectasis. Fibroid changes may follow, and bronchial stenosis is common. The formation of abundant granulations is common, and these may be found above the foreign body, evidently sometimes due to its position having shifted.

As these changes may occur in many combinations, it is evident that the resulting physical signs must

Seeds, shells, &c., removed from the bronchi.

show great variations. This is particularly marked if the blocking of the bronchus is not complete, and in this case the signs may change from hour to hour. Many of the resulting conditions require time for their development, and so the picture in acute recent cases differs much from chronic cases.

FOREIGN BODY IN THE TRACHEA.

The symptoms are usually marked and vary with several factors, of which the size and character of the foreign body are important. If the body is large enough to cause complete or nearly complete obstruction, death results rapidly with asphyxia. Many foreign bodies in the trachea are movable, and the movements may be felt by the patient. If the foreign body becomes fixed the symptoms may be few, as, for example, when the point of an open safety-pin becomes fixed in the wall of the trachea. Pain is not common, but is complained of occasionally. *Dyspnœa* is marked as a rule, and is due both to the body itself and to the subglottic swelling resulting from trauma. *Cyanosis* is usual, the degree depending on the extent of obstruction. *Cough* generally begins at once, and may be almost continuous or paroxysmal. It may suggest pertussis or may have a croupy character which always suggests subglottic swelling. Cough is most marked when the foreign body is movable, and one phenomenon of importance is the sudden shutting off of the expiratory air and of phonation during the act of coughing. A loud *wheeze* is usually present. This sound is difficult to describe, but when once heard is easily recognised. It differs somewhat from the wheezing sounds of bronchial asthma, being higher pitched and more intense. It may be heard with inspiration or expiration, sometimes with both. It is heard at the patient's mouth, either with the ear or by the stethoscope, with the bell held close to or even in the mouth. It varies greatly in loudness. It is not heard on auscultation over the chest wall as a rule. It may be heard at some distance from the patient. The designation "asthmatoid wheeze" has been given to it by Jackson. The voice may be hoarse. In some cases there is a remarkable *slapping sound* which may be present with each respiration, only with a deep breath or with the act of coughing. It was very marked in a child with a water-melon seed in the trachea, in whom the sound produced by the seed striking against the larynx could be heard at some distance. At the same time the *impact* may be felt by the finger on the trachea. There is sometimes a curious sound heard, which has been termed "tracheal flutter." The examination of the thorax shows little except on auscultation. There is no difference between the sides on inspection or percussion. On auscultation the breath sounds are usually harsh and loud, the degree of change depending largely on the degree of obstruction. If the foreign body has caused much irritation and resulting secretion, which passes into the bronchi, there are many coarse râles heard throughout both sides of the chest.

Occasionally a foreign body in a bronchus is moved upwards into the trachea, in which case there may be a sudden onset of severe symptoms. In one case this occurred while Dr. Jackson was introducing the bronchoscope. There was a sudden appearance of cyanosis which disappeared when the foreign body slipped down into the bronchus of the other lung. The passage of the body into a bronchus results in a decrease in the symptoms, and the appearance of the special signs due to blocking of a bronchus. We have observed this sudden change in both directions in several patients.

Some illustrative cases of foreign bodies in the trachea are given.

Grain of Corn in Trachea.—A boy, aged 3 years, was admitted on Sept. 6th, 1923, with the history that on August 27th, 1923, he was removing the grains from a dry cob of corn (maize) with his teeth. Suddenly he had a severe choking attack, and following this almost constant cough and wheezing respiration. The child showed marked inspiratory dyspnœa, suprasternal retraction, and depression over the lower third of the sternum, which was increased with each inspiration. The percussion note was hyper-resonant throughout. Inspiration was loud and prolonged, while expiration was scarcely heard. There were coarse rumbling sounds over the whole thorax. The slap against the larynx was well heard and felt, and the tracheal flutter was present. On bronchoscopy (Jackson) the subglottic tissue was so swollen that the sides nearly touched, and the laryngeal and tracheal mucosa was intensely inflamed. The grain of corn was found at the bifurcation partially occluding both bronchi. Tracheotomy had to be done subsequently; the child made an excellent recovery.

In this case the grain of corn had produced marked changes, and in all probability death would have soon resulted. The picture in the case of a metallic foreign body may be very much less severe, and it may remain for some time without doing serious damage.

Safety-pin in Trachea.—A child, aged 9 months, was admitted on April 7th, 1919, with apparent difficulty in swallowing. The day before the child swallowed an open safety-pin. The mother saw the pin in the child's mouth and made an unsuccessful attempt to remove it. There was no dyspnœa or cough, and the only symptom was an apparent disinclination to swallow. The examination was absolutely negative. There was no distress or dyspnœa, and no abnormal signs found in the thorax. The X ray study showed the safety-pin in the trachea, point upwards, and the keeper-end just in the opening of the glottis. There was acute laryngo-tracheitis found; the pin was removed by Dr. Jackson in seven seconds.

The *diagnosis* of a foreign body in the trachea is not difficult in the majority of cases, especially if there is a definite history of choking when there was an object in the mouth. The greatest difficulty is found in young children, especially if the history is indefinite. Subglottic swelling is common, giving hoarseness and a croupy cough. Naturally *diphtheria* is suspected, and an interesting commentary on this is the number of patients with foreign bodies in the trachea to whom diphtheria antitoxin had been given. If the foreign body shows in the X ray plates there is no difficulty. As the metallic bodies give the least in the way of symptoms and signs but show in the X ray plate, they should not be missed if the suspicion of a foreign body is entertained. With bodies non-opaque to the X rays there are usually more symptoms and signs and so the diagnosis should be suggested. The occurrence of a "wheeze," the "audible slap," and the palpation of the impact of the foreign body are practically pathognomonic. In the absence of the last two, care should be taken not to be misled by the signs of a foreign body in a bronchus for the recognition of which a proper examination of the thorax should be sufficient. To exclude *diphtheria* direct laryngoscopy with the taking of cultures is usually sufficient. Considerable difficulty arises from trauma due to a previous bronchoscopy in which nothing was found. Here the symptoms are due to swelling, and it may be difficult to pass judgment until a few days have passed. If the symptoms become so severe that tracheotomy is indicated, the diagnosis can then be made.

FOREIGN BODIES IN THE BRONCHI.

When one considers the great variety of foreign bodies that have gained entrance to the bronchi, it is evident that the resulting conditions and physical signs must vary, and it may be of value to discuss some of the factors which influence the clinical picture. (1) *Size* and *shape* of the object. This influences the situation at which the foreign body lodges and the degree of obstruction produced. In general, objects pass as far down the bronchi as possible. (2) *Character* of the foreign body. This is of great importance, especially with regard to the general reaction. For example, a closed safety-pin causes, for a time at any rate, very little reaction or inflammation. Metallic foreign bodies act by causing local irritation and obstruction to which infection and the formation of pus are added subsequently. Certain substances, in addition, set up a most intense inflammatory process, apparently through some irritant action. Nuts and other vegetable substances belong in this category, and to them special attention will be given subsequently. (3) There may be several particles of a foreign body aspirated, as, for example, when a nut is being chewed and a number of small particles pass into the bronchi. (4) The amount of resulting secretion and irritation varies.

With regard to the bronchus and lung, there are a number of possibilities which apply to a lobe or a whole lung. This is true not only as regards the affected portion of lung, but there may be a great variation as regards the condition of the other lung and the position of the heart. When a foreign body lodges in a bronchus there are several possibilities.

1. *It may plug the bronchus completely.* In this event the air in the affected lung is rapidly absorbed. With this one of two things, or a combination of both, results. The lung may collapse or there may be secretion into the air cells, and apparently an increase of fluid in the tissues so that the lung becomes "water-logged." It may be impossible from the signs over the lung to decide which is present, but if any considerable portion of lung is involved the position of the heart and diaphragm is of value. In many cases the condition seems to be a combination of collapse and increase of fluid content. Evidently the view that there may be increase of the fluid content is difficult to prove, but the points supporting it are: (*a*) signs suggesting that the portion of lung contains no air; (*b*) the X ray picture shows a dense shadow; and (*c*) the rapid clearing after the removal of the foreign body. A solid exudate could not be absorbed with the rapidity with which such a lung clears. This may require only a few hours. There is always the formation of pus below the foreign body if it is present for any time. The affected area shows limitation of movement, absence of vocal fremitus, dullness on percussion, and absence of breath sounds and râles. If the patient is seen before the air is absorbed there may be tympany on percussion. In children the note frequently has a marked tympanitic quality, sometimes over small areas and for varying periods. Difference in the degree of collapse and the amount of secretion may explain this. In children distant breath sounds may be heard, possibly conveyed from the opposite side, especially in the back. The unaffected lung shows *compensatory* emphysema.

2. *The foreign body allows air to pass in but not out.* This is associated partly with the change in the bronchi during inspiration and expiration. With the former the bronchus dilates, and so may permit air to pass the foreign body; with expiration the bronchus contracts and so may shut down tightly on the foreign body, not allowing any air to pass. (Fig. 7.) The result is that the affected lung or lobe becomes over-distended with air—*obstructive* emphysema. The percussion note shows hyper-resonance or tympany, and vocal fremitus is usually absent. The breath sounds are absent as a rule, but occasionally they are heard during inspiration. The presence of râles is variable; they are heard in some cases. The picture is in some ways much like pneumothorax. In a few cases pneumothorax has occurred, apparently from rupture of an air vesicle, but the amount of air which escapes has not been large. In other patients air has escaped into the mediastinal tissues. The respiratory movements disappear, the diaphragm is depressed, and the heart is displaced to the unaffected side. In such an event it is easy to mistake the side involved, both by the physical signs and the X ray study. The unaffected lung apparently has less resonance, and in the X ray plate shows a greater shadow in contrast to the over-distended lung.

3. There is *partial blocking* of the bronchus. In this event some air passes in and out and secretions can escape. Depending on the extent of the escape of secretions the signs change, as the relative amounts of air and secretion vary from time to time. There is decreased expansion of the affected side, and the vocal fremitus is diminished. The breath sounds are heard, usually rough and blowing, sometimes with a curious whistling or snoring character. Râles are numerous and of many kinds, but usually coarse, musical, or snoring.

Certain other factors operate to a varying degree.

1. There is nearly always some *swelling of the mucous membrane.* This tends to close the bronchus, and, in many cases in which the foreign body itself could not plug the bronchus, as, for example, a small bar pin, the resulting swelling does so.

2. *Granulations.*—These form rapidly and may play a considerable part in causing obstruction. In some cases they extend upwards in the bronchi. Thus a patient when first seen may have a foreign body blocking the lower lobe bronchus with the bronchus to the upper lobe quite open. Gradually the upper lobe bronchus becomes obstructed, and at bronchoscopy the granulations extend to the bifurcation of the trachea, the foreign body being found in the lower lobe bronchus. In many such cases strong effort, as in violent coughing, may force secretion through the granulations. The foreign body may be found embedded in a mass of granulation tissue.

3. *Secretion.*—This forms very rapidly and is always present below the foreign body. With obstruction to its escape it increases in amount and may be forced out occasionally. Air may gain entrance as this occurs. Secretions frequently pass over to the bronchi of the other lung or to an unaffected lobe and cause changes there. In some cases this is so marked that changes in the physical signs are found in the lower parts of the other lung. If the foreign body is a nut, which was being chewed at the time of aspiration, there is the possibility that small particles may have passed down to the side other than that which contains the largest portion. One point which is sometimes useful in diagnosis is the effect of atropine on the secretions. It may check the secretion so that the râles disappear entirely for a time and the character of the breath sounds can be more easily studied.

FIG. 7.

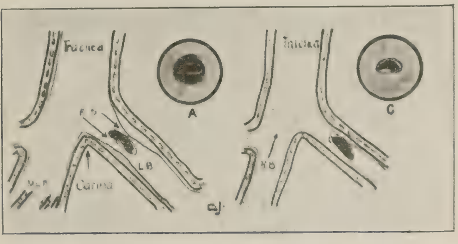

Diagram illustrating the mechanism which enables air to enter a bronchus but not to escape.

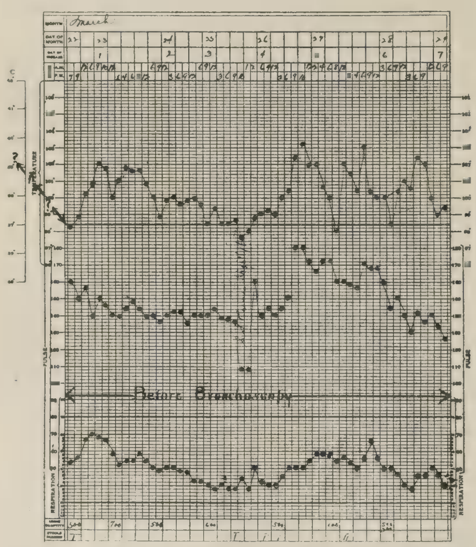
4. *Shifting of the Foreign Body.*—This is not very uncommon, and naturally confuses the signs and the diagnosis. The most frequent happening is that the foreign body is forced up into the trachea and remains there, or passes down into the bronchus of the other lung. The swelling of the mucous membrane persists for some days on the side first affected giving signs, while on the other side the foreign body causes changes. An example is as follows:—

Peanut in Bronchus.—A patient, aged 3 years, had been given candy which contained peanuts. She disposed of one piece, but with the second one she suddenly choked and became black in the face. The choking soon ceased, but dyspnœa and wheezing respiration persisted. Three weeks later the child was brought to the clinic with a temperature of 104° F., a pulse-rate of 140, and a respiration-rate of 40. The signs were in the lower right lobe. The other lobes on the right side and the left lung showed harsh breath sounds and an occasional coarse râle. The child was examined several times, and the signs were unchanged on the examination made just before bronchoscopy. On insertion of the bronchoscope by Dr. Jackson the child became very cyanotic. The *right* bronchus was found intensely inflamed and large amounts of pus appeared, but no foreign body could be found. The other side was explored and the peanut found in the *left* main bronchus. Dr. Jackson thought that the shift occurred with the introduction of the bronchoscope, and that this was responsible for the marked cyanosis. The place where the peanut had been on the right side was well marked by the local changes.

5. *The Results of a Previous Bronchoscopy.*—With the great development of bronchoscopy it is natural that some men may practise it who have not had sufficient training. One can imagine a man, who realises that his training is insufficient, perhaps thinking it is his duty to try and remove a foreign body if more skilled operators are a long distance away. Whether this view may be right or wrong, a certain number of patients are seen in whom trauma has resulted from previous bronchoscopy. This may add greatly to the difficulty of diagnosis, and time is usually required for the signs due to the bronchoscopy to subside.

FIG. 8.



Temperature chart from a patient with a peanut in a bronchus. The drop in temperature (upper curve) occurred with a period of drainage. The rapid pulse and respiration rates (middle and lower curves) are marked.

6. The many possible variations in the relative amounts of air and secretion in the affected lung may cause great changes in the signs even from hour to hour. This renders it important to study the patients —if the diagnosis is difficult—for several days with frequent examinations. Special emphasis must be placed on the varying signs. On the one hand this is confusing, but on the other hand it is sometimes very helpful, especially if there is danger of mistaking the condition for pneumonia or empyema.

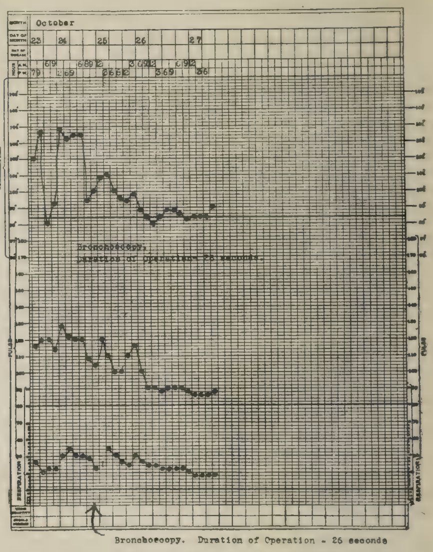
7. *Late Changes.*—These are not peculiar to foreign bodies. If the foreign body remains for a sufficiently long time a purulent process results and may lead to abscess formation. Bronchiectasis and fibroid changes are also natural sequences.

Symptoms.

The immediate symptoms due to the inhalation of the foreign body are very variable, as has been mentioned. There may be none or they are so slight as to escape notice both in adults and children. The following histories illustrate this:—

Atomiser Tip in Bronchus.—A man, aged 58 years, was troubled by cough which continued for some months, due, he thought, to his having "caught cold." He was told that many râles were present on both sides. A diagnosis of tuberculosis was made, although no tubercle bacilli were found. He went south for his health, but did not improve. Finally an X ray study was made, which showed a foreign body in the right lower lobe bronchus. On removal this was found to be the tip of an atomiser. He then remembered that 18 months before he had noted that the tip of his atomiser had been lost. He had no recollection of any disturbance which occurred at the time of aspiration.

FIG. 9.



Illustrating the rapid fall in temperature after removal of a foreign body. Pulse and respiration rates follow suit.

As might be expected, the lack of any history of aspiration is not infrequent in young children. They may not realise that anything worthy of comment has occurred or many hesitate to expose their doings to publicity and perhaps punishment.

Umbrella Tip in Bronchus.—A boy, aged 8 years, was brought with the history that when 2½ years of age he suddenly brought up a mouthful of blood while eating a meal. An attack of fever followed, and the condition was diagnosed as broncho-pneumonia. There were repeated hæmorrhages and continued cough, but it was not until five years later that an X ray study was made and the metallic tip of an umbrella discovered in a bronchus. There was nothing to suggest the time of entrance. In another patient, a boy aged 7 years, there was a history of cough for eight months, but no information could be obtained which gave any clue as to the time of aspiration. Examination showed a collar button in the lower right bronchus.

There is a great difference between the symptoms due to an irritant substance such as a nut and to a metallic structure such as a tack. The features of the former are discussed separately as they have special characteristics. In the majority of cases there is some disturbance at the time of aspiration, but this varies greatly in severity. The patients speak of choking and strangling, and the account in children is often of very severe disturbance accompanied by cyanosis. In many cases the account suggests that the object being in the trachea was responsible for the severity of the manifestations. The history often states that in a short time the symptoms decreased and the patient became comfortable, or there may have been paroxysms of cough for a few days. In some cases there are fever, cough, and rapid respiration, so that a diagnosis of pneumonia or influenza is often made. After this or without it there may be a period without symptoms. This often causes error, as it is supposed that there cannot be any foreign body present without distress. This quiescent period is responsible for many errors, and the frequency of its occurrence deserves special emphasis. Certain of the symptoms may be discussed in detail.

Cough.—This is usually present to some extent, but its occurrence may be irregular; sometimes it is in paroxysms. In small children it is often excited by movements or by crying. If an inflammatory process involves the upper air-passages or there has been trauma from a previous bronchoscopy, the cough may have a croupy character. So much has been learned from the bronchoscopic work of Professor Jackson regarding the factors which excite cough that some discussion of the whole subject is important, especially in the explanation both of its occurrence and of its absence.[3] The cough reflex may be entirely absent; this occurs most often in children and especially in toxic conditions. It is seen sometimes in old people with pneumonia. If an inflammatory process with secretion is present, marked accumulation results if the cough reflex is absent. The mucous membrane of the respiratory tract shows a marked tolerance to the irritation of a metallic foreign body after a few minutes of contact. Cough is excited if a bronchoscope is introduced into the right bronchus, but this subsides in a few minutes, and the tolerance remains until the instrument is brought into contact with new areas. If the bronchoscope is then introduced into the left bronchus and later reintroduced into the right bronchus the tolerance is found to have disappeared and cough is excited as on the first introduction. This explains certain of the clinical phenomena. For example, a foreign body which is fixed causes very little cough as compared with that resulting from a movable substance. In the former case tolerance is quickly established. This explains the frequent quiescent interval noted after the first period of cough following aspiration if the foreign body is not a plant substance.

Soon another factor comes into operation—namely, the reaction set up by the presence of the foreign body. In the case of a pin this may be very slight, but in the majority of cases there is local irritation with the production of secretion. The mechanism of the cough reflex will then be the same as in other conditions in which secretion occurs. There appears to be a difference due to the situation of the foreign body, and it seems that when it is far down in the bronchial distribution it excites less cough than if in one of the main bronchi. In one case a safety-pin remained for two months low down in the lung without exciting cough.

The influence of *secretion* is important. In almost all cases in which the production of pus occurs there is marked cough. It seems that when the foreign body is fixed the resulting cough is excited by the irritation and presence of secretion rather than from the foreign body itself. This is supported also by the fact that in cases in which the foreign body is a vegetable substance, such as a nut, and excites intense inflammation very rapidly cough results very quickly and is frequent in occurrence. The influence of secretion is also shown by the occurrence of cough in patients who have a foreign body in the œsophagus. This occurs with obstructive but not with non-obstructive œsophageal foreign body. In the obstructive cases there is an overflow of material (secretions and food) from the œsophagus into the larynx.

The tolerance of the larynx to the presence of foreign bodies is sometimes marked, and is well shown after intubation. A child aspirated a safety-pin into the larynx where it remained for three weeks. After the coughing and choking at the time of aspiration there was no cough. In two cases a cockle burr was aspirated into the larynx, and after a short period of choking and coughing the patients were free from cough. It may be said that very severe paroxysms of coughing when the foreign body is in a bronchus suggests that it is being moved about. Jackson concludes that there are no areas in the trachea or bronchi which are so specially sensitive as to deserve the designation of cough excitation areas; that tolerance is quickly established in all areas, and that the finer bronchial divisions show less cough production than the larger bronchi. The peripheral areas show no cough reflex unless *possibly* the pleura is irritated by pressure.

Dyspnœa.—This is rarely marked in bronchial cases with a metallic substance unless a main bronchus is blocked, secretions have passed over to the unaffected side, or the swelling of the mucous membrane has produced narrowing on one side and the foreign body has been shifted to the other side. The inflammatory reaction from bodies of an organic nature usually causes marked dyspnœa.

Pain.—This is rare, but in some cases the patient is able to localise the situation of the foreign body very accurately. In other cases they have been quite wrong, and have located the foreign body on the unaffected side of the chest from their sensations.

Fever is almost invariable at some time or other. (Figs. 8 and 9.) In many cases it comes on at intervals lasting for a few days or a few weeks, usually with an increase in cough and expectoration. In such cases the diagnosis of influenza or pneumonia is frequently made. With marked suppuration the fever curve may show wide variations. Slight continued or irregular fever is not uncommon.

ELLA SACHS PLOTZ FOUNDATION.—This Foundation has been established in memory of Ella Sachs Plotz, of New York City, for the promotion of scientific investigation. The income from it is to be used under the following conditions: 1. For the present, researches will be favoured that are directed towards the solution of problems in medicine and surgery or in branches of science bearing on medicine and surgery. 2. As a rule, preference will be given to researches on a single problem or on closely allied problems; it is hoped that investigators in this and in other countries may be found, whose work on similar or related problems may be assisted so that more rapid progress may be made possible. 3. Grants may be used for the purchase of apparatus and supplies that are needed for special investigations, and for the payment of unusual expenses incident to such investigations, including technical assistance, but not for providing apparatus or materials which are ordinarily a part of laboratory equipment. Stipends for the support of investigators will be granted only under exceptional circumstances. The present available annual income is $10,000. Applications for support from this Foundation, accompanied by a full statement of the need for the investigation, the conditions under which it is to be prosecuted, and the way in which the grant would be expended should be forwarded to the Secretary of the Executive Committee, Dr. Francis W. Peabody, Boston City Hospital, Boston, Massachusetts.

LONGEVITY OF PARASITIC WORMS:

THE TERM OF LIVING EXISTENCE OF SCHISTOSOMA HÆMATOBIUM IN THE HUMAN BODY.

By J. B. CHRISTOPHERSON, C.B.E., M.D. CAMB., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL, VICTORIA PARK; LATE MEDICAL DEPARTMENT, SUDAN GOVERNMENT.

LONGEVITY in biology is the term of living existence, without reference to its being a long or a short term or comparatively a long or a short term. The word needs definition because, being one about which dictionaries are not precise, its meaning is ambiguous. In an essay on comparative longevity, published about 1870, Ray Lankester[1] found it necessary to define its uses. Chalmers-Mitchell, in his Notes on the Theory of Longevity,[2] accepts Ray Lankester's definitions, and we cannot do better than accept them also.

Longevity: Normal and Potential.

Ray Lankester refers to "specific longevity" as the average span of life of the species, and "potential longevity" as the possible length of life of the individual. Specific longevity is the longevity of the species, the length of time a living being may expect to survive under natural conditions—the "expectation of life at birth." This is a problem of mathematics rather than physiology, is largely determined by accidents and external conditions, and does not interest us here. Potential longevity, on the other hand, depends on the inherent *vitality* of the individual. Accidents, diseases, and external conditions have no relation to it. It is said to be *normal* or *absolute*. If all untoward external conditions, diseases, and accidents could be eliminated, the animal surviving as long as his store of vitality lasts, no longer and no shorter, we should have absolute potential longevity, and the biologist could study longevity without any qualifications.

Absolute potential longevity is rarely if ever attained; we must therefore examine longevity as we find it, normal potential longevity, length of life under normal conditions. Although the subject of potential longevity has been much studied by philosophers and biologists, no great distance has been traversed, possibly because investigations have been limited in the main to man and the higher animals. The question as to why one animal lives longer than another is still without a satisfactory answer. Is there in truth any causative relation between high longevity and complex structure or mass? Has personal energy or generative expenditure anything whatever to do with potential longevity? Why is the distribution of "vitality" apparently so arbitrary?

Practically speaking, little is known of the potential longevity of the higher animals[3]; of that of wild animals nothing. Of potential longevity we know little concerning domesticated animals, and nothing concerning the uncivilised races of man, and we have only a life-insurance office knowledge concerning civilised man; accidental influences obscure the path of investigation, making progress by scientific methods impossible. Under such circumstances longevity can be dealt with mathematically but not biologically; in other words, specific longevity may be determined in the case of some of the higher animals, but it is difficult, if not impossible, to determine potential longevity.

More precise knowledge is obtainable of the potential longevity of some of the lower forms of life, and here the problem seems to be simpler. For instance, the plasmodium of malaria has a well-known term of existence in the human circulation[4] and the longevity of some of the parasitic trematode worms have been studied. Thus there appears a prospect of increasing the slender store of knowledge by the study of tissue and blood parasites in connexion with longevity, especially in such cases where external influences are reduced to a minimum—as, for instance, in fluke parasites of animals, where normal and absolute longevity approach each other more nearly than in other living things.

The Bilharzia Worm.

The potential longevity of the bilharzia worm in the human body is well worth attention. It is a tissue and blood parasite, and as such little subject to changes in environment, surroundings, or external conditions. G. M. Vevers,[5] in a review of the entozoa collected from animals which died in the Zoological Gardens of London during eight months in 1919, reporting a case of *Gastrodiscus ægyptiacus*, the trematode of equines in Africa, draws attention to the small amount of information we possess on the length of life of parasites of various groups in their hosts. (*Gastrodiscus ægyptiacus* is a species of parasite not altogether unrelated to bilharzia.) Dr. Vevers found this parasite in a Grevy's zebra which had been in the Gardens for six years. As it does not breed in the host, but requires an intermediary host to complete the life-cycle (*Cleopatra bulimoides*, a fresh-water snail), and as an intermediary host has not yet been reported in this country, the parasite must have been six years old at least at the death of the zebra. Further, as the zebra was in Hagenbeck's collection at Hamburg for three years previously we may fairly certainly assume that the potential longevity of *Gastrodiscus ægyptiacus* is at least nine years—probably longer. This is a long time for a parasite to live in the body of the host, and, as Dr. Vevers points out, the more remarkable in that the parasite lived in the intestines, where the vicissitudes of existence are greater and more numerous than in the blood or tissues. But remarkable as is this evidence of great longevity in a small living thing, it is not so remarkable as the long span of life of the bilharzia worm.

During the South African war many British soldiers contracted bilharzia disease. In 1920, 18 years after, many of the survivors, who had not been out of England and so could not have been reinfected, were passing live ova in the urine; in other words, some of the worms which the men had acquired in South Africa in 1902 were alive in 1920. The potential longevity of the bilharzia worm must therefore be 18 years. It is in point of fact longer. A well-known zoologist and doctor of medicine, living in England, contracted bilharzia in 1878, when he was 28 years of age, between the Limpopo and Zambesi rivers, whilst on a naturalist's expedition. He was probably infected in the Northern Transvaal on the borders of the Kala Hari river. He read a thesis on Endemic Hæmaturia in 1881, for which he obtained his M.D. degree, and became an acknowledged authority on bilharzia disease. Twenty-eight years after his return to England he was passing ova in the urine, which hatched out. He identified the ova himself under the microscope; the observation was confirmed by a well-known surgeon at Cambridge, who had often seen bilharzia ova, who made a note of the fact and informed the writer of this article. The patient had not been out of Europe in the interval, and had run no risk of reinfection by the parasite. How many years after the 28 he continued passing live ova I do not know; he did not bother about a disease which he had had for so long. I saw him in 1920 (42 years after infection), and found no ova in the specimen of urine which I examined, so 28 years must stand for the time being as the longest life of the bilharzia worm yet recorded. Possibly the potential longevity of the worm is longer; my friend wrote me in 1923 that he was of opinion that some of the worms still survived (45 years after infection) for he was still bothered by urinary irritability every year in August and September, which he humorously regarded as an indication that " Bill " was, as usual, taking the family to the seaside for the summer holiday.

[1] On Comparative Longevity in Man and the Lower Animals, 1870.

[2] Proc. Zool. Soc., 1911, i., 430.

[3] Ray Lankester's expression in 1870 was "profound ignorance."

[4] The longevity of the plasmodium of malaria may not be so simple as appears from this statement; it apparently may assume a spore form and lie dormant in the body for a long period.

[5] Proc. Zool. Soc., 1920, Pt. III., 805.

With regard to the general question of the longevity of bilharzia worms, bilharzia, practically speaking, is always a multiple infection. We have counted at Khartoum as many as 450 worms in the portal vein of a case post mortem—each worm is a separate individual infection. There may be many strains of worms in the same human host, each strain having its own potential longevity. Some of the worms, no doubt, die each year, it being common experience, if no complications intervene, that symptoms improve with time. The weaker strains die first, and those with higher potential longevity live longer, it may be over 20 years, while a few live longer still.

The reason of the variability in the longevity of individual worms is an interesting question. Is it that different strains have arrived at various stages in their endeavour to adapt themselves to the span of life of the host? A tissue and blood parasite, subject to no adverse external influences to speak of, with no great changes in environment, no anxiety about food, &c., the only accident to which it is liable being the death of the host, would be more likely than another to live out its full span of life, fulfilling its destiny, and adapting itself to the span of life of its host more rapidly on this account. The longer-lived worms of the brood endowing their progeny with higher potential longevity than the shorter-lived, one might suppose the longevity to increase as generation succeeded generation. Bilharzia is an ancient disease in Egypt; it possibly originated there. It was prevalent about 1000 B.C.,[6] and the early papyri (Ebers) record a remedy for hæmaturia.

Relation of Longevity in Parasite and Host.

The worm having probably had time to adapt itself to the life-span of the host, one might expect parasites of a host with a shorter potential longevity than man to have a shorter potential activity than bilharzia worms. In the case of trematodes, cestodes, and nematodes[7] with intermediate hosts, when the patient has been moved from the focus of infection to a non-infected locality and the danger of reinfection eliminated, the longevity of the parasite can be studied with a fair amount of certainty, as we have an approximate date of infection and external harmful influences are reduced to a minimum. If certain parasites have potential longevity corresponding to the average longevity of the host, we might expect to find that the longevity of the bilharzia worm infecting cattle was of shorter duration than that infecting human beings.

It has been suggested to me that some of the diptera lay many eggs and have short longevity, and that parrots lay two eggs in about three years and have high longevity. Let these facts be admitted. It is not clear that the diptera die early because they lay many eggs, or that the parrot would live a shorter time if she laid more eggs. Bilharzia lays many eggs and has long potential longevity. If bilharzia did not lay many eggs the species would not be carried on—of the total number of miracidia hatched few have the chance to reach the intermediate host—but, on the other hand, one single miracidium piercing a snail may give rise to many cercariæ.

It seems to me that no conclusion can be drawn from these facts. There is a stranger thing to relate—namely, that the cercaria, the larval form of bilharzia, has a maximum longevity of about 28 hours as a free swimming entity, but when it pierces and penetrates the human skin it discards its tail and develops into the bilharzia adult worm having a potential longevity of 28 years. Can this be explained in general terms?

Conclusion.

To conclude, it seems clear that bilharzia worms have a long potential longevity, and do not conform to the conditions which Ray Lankester has laid down as favouring longevity. Their *individuation* is not high, their structure is not complex or their bulk large. They display considerable energy throughout their (frequently) long life, traversing the portal veins between the liver and bladder (or rectum). Their generative energy is great, commencing early and continuing through life; they deposit enormous numbers of eggs.

It is probable that the study of the life-history of living things shorn of most of the obscuring and overwhelming external conditions of environment will bring us nearer to fundamental principles which apply to more complex and more developed organisms and lead to a revision of our present conclusions regarding potential longevity.

[7] In the Ministry of Pensions tropical clinic the following case recently occurred showing the longevity of filaria: An Englishman was infected with *Filaria loa loa* in West Africa. He was placed under observation in 1918 and his peripheral blood was at intervals examined, but it was not until 1922 (6½ years after he first noted the swellings (Calabar)) that embryos occurred in the blood-stream. As *Filaria loa loa* requires an intermediary host to carry on the species not found in England, and as the man had not been out of England since 1915 he could not have been reinfected, we must conclude that the filaria worm producing the embryos arrived at maturity after 6½ years. It will be interesting to know what the potential longevity of *Filaria loa loa* is. The infection has already existed for nine years (1924) in the case quoted.

IDIOSYNCRASY TO ADRENALIN,

WITH REFERENCE TO ITS EMPLOYMENT WITH LOCAL ANÆSTHETICS AND IN GOETSCH'S TEST FOR HYPERTHYROIDISM.*

BY H. E. SYMES-THOMPSON, M.D. CAMB.,
M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL CHEST HOSPITAL, CITY ROAD.

AT the joint meeting of various Sections of the Royal Society of Medicine on cocaine substitutes, as reported in THE LANCET of Dec. 15th, 1923, adrenalin, which is often given with drugs of this class, received little notice when toxic effects were being reviewed. Adrenalin is not a cocaine substitute, and it was not, strictly speaking, under discussion. It seems, therefore, a suitable time to consider its toxic effects.

The Employment of Adrenalin with Local Anæsthetics.

The following instance of the occurrence of disquieting symptoms after the injection of novocaine and adrenalin for the extraction of teeth has recently come to my notice. Incidentally, the patient gave a positive reaction to Goetsch's test for hyperthyroidism, though the dentist did not have this test in view when making the injection.

A married woman of average nervous stability, aged 38, had novocaine and suprarenin injected into the gum by Mr. S. D. Corbett for the extraction of two lower incisor teeth on July 2nd, 1923, and the following symptoms appeared almost immediately after the injection: limpness and chilliness, succeeded by mental agitation, severe palpitation, rapid panting breathing, flushing of the face, and tremor of the arms and legs. The pulse was feeble. There was no nausea and the brain remained clear. A few minutes later, the severity of the symptoms having abated, the teeth were removed. On getting up there was difficulty in standing. Recovery was uneventful, and the patient was in her usual health the following morning. The doses of the drugs injected were 0·03 g. (½ gr.) of a 2¼ per cent. solution of novocaine and 0·00003 g. of suprarenin—an amount equal to ½ a minim of a 1 in 1000 solution of adrenalin chloride, at a strength of 1 part in 40,000.

Dixon[1] states that suprarenin, which is synthetic adrenalin, has only half the toxicity of the natural variety, so the appearance of toxic symptoms in this case, following, as they did, so small a dose, is the more striking. On inquiry, it transpired that the patient had experienced similar, though less marked, symptoms several times previously in similar circumstances. Their greater severity on this occasion may be attributed to the fact that she was at a lower level of health at the time.

---

* Based upon a paper read before the Royal Society of Medicine (Section of Therapeutics and Pharmacology) on April 8th, 1924.

The symptoms might be explained on the assumption that the drug was injected into a vein—intravenous injection of adrenalin being 40 times more dangerous than subcutaneous [2]—but this contingency is excluded here, as the patient had had similar experiences before. When troubles are recorded in the literature in connexion with the use of novocaine and adrenalin for tooth extraction, one cannot always be sure that neurosis, or some other cause, has not played a leading part in their production. On the other hand, patients actually presenting mild toxic effects have, no doubt, been diagnosed as showing manifestations of neurosis. I may, however, draw attention to a case, recorded by Parfitt,[3] in which novocaine and adrenalin were injected for tooth extraction, which presented symptoms strikingly resembling those of the case detailed above; and to another, published by Pedley,[4] in which death occurred in similar circumstances.

But grave toxic symptoms following the use of small doses of adrenalin in dental practice are not common, for Mr. F. N. Doubleday, at the meeting of the Royal Society of Medicine above referred to, stated that he had used novocaine and adrenalin in hospital practice for 16 years without serious ill-effects.† Nevertheless, it is recognised that adrenalin is liable to cause disquieting symptoms, even in small doses, unless used in dilute solutions, for Blomfield [5] writes: "Adrenalin, if injected in too strong solution, easily causes a feeling of oppression in the chest and palpitation." Blomfield [5] further states that "the local ischæmia produced by adrenalin follows the use of solutions as weak as 1 in 200,000." In view, therefore, of the existence of individuals with an idiosyncrasy to adrenalin, it would appear that dentists might, without sacrificing efficiency, use a solution of a strength of 1 in 100,000 to 1 in 200,000 instead of one of 1 in 20,000 to 1 in 40,000. At all events, it would seem to be desirable for them to inject a small and dilute dose when operating on a patient for the first time, and, if an idiosyncrasy is found to exist, to advise a general anæsthetic on future occasions.

To turn to less minute doses, A. F. Hertz[6] gave himself a subcutaneous injection of 3 minims of a 1 in 1000 solution of adrenalin, and describes the results as follows: "I felt extremely ill for some minutes, my hands shook so much that I could hardly put the syringe away, and my pulse became very rapid." And Braun[7] gave himself a subcutaneous injection of 7·5 minims of a 1 in 1000 solution of suprarenin with the following results: A sense of oppression in the chest came on in five minutes, and the breathing became deeper and more rapid. Palpitation followed, the pulse increasing from 64 to 94 per minute, and he had to lie down. The symptoms lasted for one and a half minutes.

With still larger doses, such as those used in surgical practice, the danger of toxic symptoms is proportionately greater, and I would suggest that it is desirable to test the susceptibility of the patient by giving a preliminary dose, smaller than the one which it is intended to use at the operation, in all cases in which it is proposed to employ adrenalin in conjunction with a local anæsthetic. This remark has particular cogency in connexion with operations which are not essential. In conditions in which hyperthyroidism is known to exist, such as Graves's disease, even of mild grade, adrenalin would appear to be contra-indicated.

I may here cite particulars of a fatality which occurred at a London hospital after the injection of adrenalin in the case of a patient with Graves's disease, on whom it was intended to operate. The particulars were related to me by one of the authorities concerned, and are transcribed from notes made at the time.

> The patient was a woman of 28, with slight symptoms of Graves's disease and a goitre of considerable size. She was not nervous or apprehensive, the reason for the operation being her desire to have the tumour removed to improve her personal appearance. At 9.15 A.M. omnopon, gr. $\frac{1}{3}$, scopolamine, gr. 1/100 and atropine, gr. 1/120 were injected, but took only slight effect, the patient not becoming drowsy. At 10.15, 65 c.cm. of a $\frac{1}{3}$ per cent. novocaine solution, and a little more than 2 c.cm. (37 minims) of a 1 in 1000 adrenalin chloride solution were injected into and under the skin of the neck, there being no evidence of the piercing of a vein. No ill-effects were noticed till 10.27, when she vomited. At 10.30 the face had become blue, the corneæ insensitive, the pupils dilated, and the breath gasping, and the pulse was only just palpable. Shortly afterwards respiration ceased, and the pulse became imperceptible. There was no response to oxygen insufflation, caffeine injection, or artificial respiration; and only a flutter was elicited by the hand when the heart was massaged through an abdominal incision.

This case shows the sledge-hammer effect of a large dose of adrenalin, when hyperthyroidism is present, and it does not, therefore, present the typical reaction associated with small doses.

The question may be asked: could not the symptoms manifested in the various cases mentioned be produced by the novocaine and not by the adrenalin? The two following considerations are opposed to this view: (1) The similarity of the picture to that following Hertz's and Braun's experiments on their own persons with adrenalin—to which attention has already been called—and also to that of a positive reaction to Goetsch's test, to be shortly described. (2) The low toxicity of novocaine. This drug has been found experimentally to be the least toxic of local anæsthetics.[8] Braun states that he has never noticed any disturbance resulting from a subcutaneous injection of a 2 per cent. solution of novocaine, and that he has been in the habit of using between 100 and 200 c.cm. of a 0·5 per cent. solution, together with small quantities of a 1 per cent. solution, repeatedly giving as much as 250 c.cm. (1·25 g.), and he quotes instances of large doses injected by others. Though he mentions several cases in which death followed the use of novocaine, he considers that other causes would account more naturally for the event in each instance. The fact that such large quantities of novocaine can be employed with impunity, if a dilute solution is used, suggests that, in addition to the initial one, further injections might be made as an operation proceeds. If this is so, the localising effect of adrenalin may not be so necessary as has been thought, and it may be possible largely to dispense with the drug for this purpose.

Certain observations on the blood pressure of anæsthetised animals by Sternberg[9] also tend to discourage the use of adrenalin in association with novocaine. These observations show that the action of adrenalin‡ is increased, as compared with its action on animals used as controls, as a result of giving even small doses of cocaine, alypin, or novocaine. The sensitising effect of novocaine was, however, much more transient than that of cocaine or alypin.

Goetsch's Test.

Goetsch's test, which is used to differentiate hyperthyroidism from certain functional nervous disorders and from early tuberculosis, may be described as follows: 7·5 minims of a 1 in 1000 solution of adrenalin chloride are injected subcutaneously. The blood pressure and pulse-rate are taken before the injection, and every few minutes after it, for a period of one and a half hours. A positive result consists in a rise of at least ten points in both blood pressure and pulse-rate during the first quarter of an hour, together with heart consciousness, asthenia, a feeling of dread, tremor, pallor, and flushing, and some sweating. Goetsch[10] was led to elaborate this test after collating the results of certain experiments on animals by various workers, from which he concluded that an increased sensitiveness to adrenalin, on the part of the sympathetic nervous system, exists in the presence of an increased amount of thyroid secretion in an organism; and that, by virtue of this sensitising action on the sympathetic system, a sudden increase of adrenalin in the circulating blood should call forth active responses throughout that system. He considers that the most frequent cause of this condition of increased activity of the sympathetic is hyperthyroidism. Whatever the theoretical basis may be, there is little doubt that adrenalin produces the results claimed in cases of hyperthyroidism. Goetsch himself obtained a positive response in cases of Graves's disease and in adenoma of the thyroid, and McBryer[11] has published a series of observations pointing in the same direction.

---

† He uses 0·02 g. novocaine and 0·0005 g. adrenalin in 1 c.cm.—i.e., at a strength of 2 per cent. and 1 in 20,000 respectively.

‡ Sternberg injected the adrenalin intravenously, and at a strength varying between 1 in 200,000 and 1 in 1,000,000.

Goetsch writes: "In no case were dangerous symptoms observed after the dose of adrenalin which I used," and he goes on to say that it is not until twice the dose is reached that mild symptoms are produced in normal individuals. In view of the various experiences narrated above, it is difficult to avoid the impression that Goetsch and certain other writers on the subject have been fortunate. Although grave symptoms may be rare, one cannot be sure how near a case, apparently presenting mild toxic effects, may be to the borderline dividing the harmless from the dangerous. But even if grave symptoms could be excluded, the manifestations constituting a positive reaction to the test, though not in themselves necessarily serious, might produce, in the case of nervous patients, psychological effects causing undesirable results of a permanent character. McBryer performed the test on a series of individuals. The series was made up of normal and tuberculous persons, some of the latter being known to have hyperthyroidism. In every case of this series tremor and nervousness were produced or increased, and in those which were known to have hyperthyroidism the pulse became "irregular, unequal, and varied in volume." Probably few physicians would agree to their patients being subjected to the test if they were aware that it is liable to produce such results as these, unless the diagnosis was impossible by other means.

As to the rôle of Goetsch's test in differentiating between hyperthyroidism and early tuberculosis there are other methods available for the purpose, and the test may therefore be regarded as a luxury. The only tuberculous cases in which, in my experience, the differential diagnosis has been doubtful have been those with acute pulmonary tuberculosis in an early stage, when the progressive nature of the lesion has rapidly decided the point. Owing to lack of experience in the diagnosis between hyperthyroidism and "certain functional nervous disorders," I am unable to give an opinion as to whether the advantages to be expected from the test in this type of case are commensurate with the inconveniences and risks entailed.

Conclusions.

That some people show toxic effects, as a result of receiving a small dose of adrenalin, and that these effects are increased if certain local anæsthetics are given simultaneously.

That toxic manifestations from adrenalin might be eliminated in dental practice if dentists were to avoid stronger solutions of this drug than 1 in 100,000.

That surgeons might escape such manifestations by giving a preliminary injection of a smaller dose of adrenalin than that which it is proposed to employ at the operation; and, in the event of an idiosyncrasy to adrenalin being found to be present, by employing a general anæsthetic.

That it is preferable to use synthetic adrenalin rather than the natural product.

That the use of adrenalin is contra-indicated when operating on patients with Graves's disease.

That the practicability of using large quantities of a dilute solution of novocaine may render it possible to discontinue the use of adrenalin with this local anæsthetic.

That Goetsch's test should only be employed when the diagnosis cannot be established by other means; and that, if it is decided to make the test, a smaller dose should be given first, as suggested in the case of projected surgical operations.

MEASUREMENT OF ULTRA-VIOLET LIGHT

BY MEANS OF AN ACETONE METHYLENE-BLUE SOLUTION.

By A. WEBSTER, F.C.S.;

LEONARD HILL, M.B. Lond., F.R.S.;

AND

A. EIDINOW, M.B., B.S. Lond.

(*From the Department of Applied Physiology, National Institute for Medical Research, Hampstead, N.W.*)

The first essential in the proper use—as a means of treatment—of sun radiation or that of artificial sources is an accurate measurement of dosage. The dose is the product of intensity and duration. It has been shown that it is the ultra-violet radiation which is active in producing biological action, such as erythema followed by pigmentation of the skin, prevention of rickets in animals and children on a deficiency diet, and cure of lupus and other tuberculous lesions. Infra-red rays by themselves have no lethal action other than that of heat, as is shown by the fact that if infusoria, microbes, or the human skin be kept cool—e.g., by irrigation—infra-red rays have no effect. Both these and visible rays, in so far as they heat the living cells, quicken the lethal action of ultra-violet rays.

While the biological action of the ultra-violet rays is thus quickened by coincident infra-red and white light, there is some evidence that, at any rate in the case of the mercury-vapour lamp, it is somewhat delayed in cool conditions by a coincident pencil of red-yellow rays. The chief artificial sources of ultra-violet rays are the carbon arc and the mercury-vapour lamp. Metal cores are introduced into a carbon pole to increase the ultra-violet radiation and biological activity of the arc. Tungsten has been used, but we find the cheaper aluminium cores to be more active. The spectrum of tungsten is credited with no lines shorter than 3965 Angström units, while that of aluminium extends to 2263 and iron to 2332. That of iron is particularly rich in lines about 3000, which is the length of ray most active in producing erythema of the skin. The ordinary "white light" carbon is itself not far behind the metal-cored ones, and is quite active enough for general use. The carbon arc is rich in visible and heat rays, but not so rich proportionately in visible rays as the high sun. The mercury-vapour lamp (M.V.L.) is richer in ultra-violet rays, and gives off much less heat and less visible rays than the carbon arc. In the Cooper Hewit M.V.L. the arc is made in a vacuum, and the intensity of this lamp falls off as the vacuum becomes lessened with time. In the Kelvin, Bottomley, and Baird M.V.L. there is no vacuum, and the same disadvantage does not occur, but deterioration takes place slowly. It is necessary that the intensity of the M.V.L. should be tested from time to time, and that of the carbon arc measured before treatment is given. As the intensity varies as the square of the distance from the source, very different dosages may be given, and either uselessly small, or harmfully large, reactions produced if the dosage is not measured beforehand.

The sun varies enormously with its height in the sky and with clarity of atmosphere, amount of cloud, &c. A gauge is required both to test the strength of the sun before dosage and to measure the dosage given day by day. Seeking for a gauge of ultra-violet rays, based on biological action, we first began by trying the bleaching of various solutions of protein and methylene-blue, and then turned to a solution of acetone methylene-blue as simpler and cleaner and having a suitable absorptive power.

A solution of acetone in water is decomposed by ultra-violet light with the formation of acetic and formic acids and other substances. We first used the increase in pH of a watery solution of acetone exposed to a source of ultra-violet light as a measure of the intensity of the light, and in the laboratory this gives satisfactory results. It needs, however, some care in measuring quantities of solution and indicators used, and is not simple enough for general use. The decomposition of aqueous acetone by light is partly an oxidation process, and it was thought likely that reduction processes were taking place at the same time, and that these might be measured by means of the reduction of methylene-blue. This proved to be the case, the bleaching of the methylene-blue being proportionate to the time of exposure. Methylene-blue evidently acts as a hydrogen receptor in the complex oxidation and reduction processes going on in the mixture. Mr. F. Smiles investigated for us the absorption of the spectrum of the iron arc by a 30 per cent. solution of acetone in a quartz container in a layer 3 mm. thick, and by this, and by our acetone methylene-blue solution in like thickness, all rays shorter than 3600 A.u. were absorbed. The shortest visible rays are about 4000 A.u., and the shortest ultra-violet which penetrate air about 2000 A.u. The standard acetone methylene-blue is made up from a 0·1 per cent. solution of Paulenc Fréres methylene-blue; 5·8 c.cm. of this is added to 30 c.cm. of acetone and made up to 100 c.cm. with water; this gives a standard labelled (10).

Older Methods.

The older methods[1] which have been employed are (1) the iodine method of Bering-Meyer[2]; (2) the Eder photometer; (3) the photo-electric cell of Elster and Geitel used by Dorno; (4) the chron-actinometer of Bordier; (5) the silver-citrate method of Victor Henri; (6) the aktinimeter of Fürstenaus. The Bering-Meyer method depends on the setting free of iodine out of an acid solution of potassium iodide. The iodine set free by radiation is found by titration with a solution of sodium thio-sulphate, or determined colorimetrically.

Keller[3] has modified the Bering-Meyer method by mixing solutions of sodium thio-sulphate, acid potassium iodide and starch, and finding when a blue colour just begins to appear. He uses a mixture of 25 c.cm. of 1 per cent. potassium iodide solution and 25 c.cm. 5·3 per cent. sulphuric acid solution and starch, and 1 c.cm. of 1/400 n. sodium thio-sulphate solution, and using two mercury-vapour lamps, gets good agreement between the reading of this gauge and the amount of erythema of the skin produced by either lamp. One disadvantage of this method is the instability of the solution. The reaction also comes off under a glass screen and is a measure, not of ultra-violet rays, but of these and visible rays.

The Eder[4] photometer is one with a wedge of gelatine of increasing greyness with a scale printed beneath it. Sensitive paper of a standard make is placed beneath the wedge in a frame and exposure of the wedge made beneath a suitable roughened glass which diffuses the light and prevents reflection (Dorno). The extent of the scale printed off on the paper is read. This is a measure of shorter visible and ultra-violet rays. In the Bordier actinometer[5] there is a scale of coloured papers with which is compared a piece of blotting paper first dipped in 20 per cent. potassium ferrocyanide and then exposed to light. We have tested this method under quartz and under glass screens. That under quartz colours the quicker, but the reaction is very slow—e.g., exposed to 25 amp. arc, slight coloration occurred in 90 minutes—while an erythema of the skin followed a 15 minutes' exposure, and the acetone methylene was bleached 1·0 on our scale by an exposure of one hour.

The aktinimeter of Fürstenaus[6] depends on the increase of electrical conductivity of selenium on exposure to light. Victor Henri[7] investigated the following methods for gauging ultra-violet:—

(1) Dissociation of pure and dry HCl.

(2) Decomposition of H_2O_2 in pure H_2O. This is made ten times slower by a glass screen 1 mm. thick in front of the M.V.L., the glass cutting off the shorter ultra-violet rays.

(3) Decomposition of cane sugar and increase of H-ion concentration measured by the physical method. The glass screen slows this 15 to 20 times.

(4) Decomposition of KI in the presence of H_2SO_4. The glass screen slows this 4 to 5 times.

(5) Decomposition of paper moistened with silver citrate. The glass screen slows this 8 times.

(6) Sterilisation of *B. coli* emulsion, 100 c.cm. in a porcelain capsule 6 cm. in diameter placed 20 cm. from M.V.L. The glass screen slows the sterilisation 1000 to 2000 times.

We find that the silver citrate paper exposed to the 25 amp. arc blackens almost as quickly under glass as under quartz. It measures visible and ultra-violet rays. The rays which have the most active biological action on the skin are the middle ultra-violet ones, those at and just on either side of 3000 A.u.[8] These are the shortest rays present in the high sun on clear days, which particularly produce sunburn and pigmentation. Longer ultra-violet rays of equal intensity do not have so great a biological action, but these act on the skin when sufficiently intense in arc or high sun. Shorter ultra-violet rays do not penetrate to the deeper cells of the epidermis, and so while very powerful in killing unicellular organisms into which they penetrate, have little or no action on the skin. Comparing the bleaching of acetone methylene-blue with the action on infusoria in quartz tubes and on the human skin we find a general agreement. In the case of the M.V.L. it takes twice as long to bleach our standard acetone methylene-blue solution one point in our scale as to kill infusoria, or to produce an erythema in the skin equal, on the Lovibond tintometer scale of coloured glasses for skins, to 1·0 yellow plus 1·5 red. In the case of the carbon arc longer ultra-violet and the heating effect of infra-red and visible rays so increase the biological action of the middle ultra-violet rays that the bleaching time for acetone methylene-blue one point in the scale becomes four times as long as that of the above biological reactions. In the case of the autumn and winter sun the bleaching time appears to be twice as long as that for producing the biological reactions; we have not yet had opportunity of investigating the high spring and summer sun.

Details of Method.

Preparation of Standard Acetone Methylene-blue Solution and Standard Quartz Tube.—Take two parts of the standard methylene-blue solution and add one part of acetone and mix. This is the solution used for filling the standard quartz tube. The mixed solution very gradually fades and must be kept in a stoppered bottle in a cool dark place. The standard quartz tube is one with internal diameter of 3 mm.

Instructions.—Fill quartz tube to within ¼ in. of top and close tube with rubber cap, place it against the standard tubes and determine its strength, and then expose to sun or source of radiant energy. By determining the strength of tint before exposure errors due to fading or refractive power of the quartz tube are avoided.

Exposure.—The tube is exposed in an open space that is not shaded in any way from the sun, and is best placed horizontal and with the length of the tube facing zenith.

Time.—In winter, in Britain, the tube can be exposed from 9 A.M. to 9 A.M., and the reduction for the whole day determined. In spring and summer on sunny days the time of exposure may have to be shorter, from, say, 10 to 4, the time during which heliotherapy goes on. In the Alps, where cool early morning hours and less powerful sun are used for treatment, the intensity in these hours would be measured. At the end of the exposure compare the colour in the quartz tube with the colour of the six standard tubes. The standard tubes are marked 3, 4, 5, 6, 7, 8, 9, and are placed in a suitable frame for comparison.[9] If by any chance the sun is so strong as to completely bleach the acetone methylene-blue solution, then the time of exposure must be shortened.

When comparing the exposed tube with the standards hold the tubes at an angle of 45 degrees against the white paper background. Each standard tube is sealed up after the introduction of the watery solution of methylene-blue, which for tropical countries is suitably "buffered" with phosphate salt so as to prevent any alteration of alkalinity and colour of the solution through the prolonged contact with glass in warm atmospheres.[10] After filling the quartz tube, it is advisable to polish it on the outside with a clean piece of cotton—i.e., a soft handkerchief. Any grease or dirt on the outside will stop the ultra-violet rays from penetrating into the solution.

On a clear day the blue sky reflects and scatters much ultra-violet light; white clouds also give these rays. The total ultra-violet from the blue sky is greater than that from the high sun, and much greater than that from the low sun (Dorno). On clear days the sun and sky together produce the result. On cloudy days the intensity of the ultra-violet rays from the sky are measured. Notes of the conditions at the time of exposure are useful: the height of the sun above the horizon, clear or cloudy sky, &c., temperature of air, black fur temperature, and cooling power determined by the kata-thermometer.

In measuring the intensity of lamps the quartz tube is placed vertically—i.e., at right angles to the lamp—and on the same level as it. In measuring the treatment of any particular case, the quartz tube can be placed at the same distance from the lamp as the body, and exposed for the same time as the patient. A rise in temperature of 10° C., say from 15° to 25° C., accelerates the bleaching and makes the reading about 0·6 too high. A correction can be made then for temperature, but as warmth also accelerates the action of ultra-violet rays on the skin so far as concerns treatment, this is unnecessary.

Examples of Results.

Commander Dudding, of the *Hood*, wrote: "I got no reading from my quartz tubes daily exposure two hours (1200 to 1400) until we got to the Cape, lat. 25° S., 12° E. When I got '6' at the same time, men's arms and legs showed red sunburn for the first time." Off Sierra Leone the climate was hot, muggy, uncomfortable—dry bulb 81 and wet 81, dry kata-thermometer 2 and wet 13, but neither sunburn nor bleaching of the blue occurred.

At a distance of 2 feet from a 25 amp. carbon arc the acetone-blue solution was bleached 1 degree in the scale in just about one hour. The Kelvin, Bottomley, and Baird mercury-vapour lamp produced the same change in about 30 minutes at 1½ feet. A 15 minutes' exposure of the body to either lamp produced an erythema of that moderate intensity indicated by the Lovibond tintometer as given above.

Exposing the quartz tube from 9 A.M. to 9 A.M. on days in January (1924) at Hampstead, the bleaching is less than 0·5 on cloudy days, 1½ on fine days, and 2½ on an all-sunny day. At Peppard Common Sanatorium, Oxon (Dr. P. Tozer, observer), the bleaching on some days may be greater by 50–100 per cent. than that at Hampstead, owing to the absence of smoke pollution there.

MASSIVE DOSES OF DIGITALIS IN AURICULAR FIBRILLATION WITHOUT HEART FAILURE.

By JULIUS JENSEN, M.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER, THE MINISTRY OF PENSIONS HOSPITAL, ORPINGTON, KENT.

FOR some years digitalis has been administered in larger doses than was customary before Sir James Mackenzie's observations on its use in auricular fibrillation. But with these larger doses of 1 to 1½ drachms of the tincture a day there remains the disadvantage that beneficial effects are not demonstrable until after the third day of administration. In 1916 Eggleston proposed to use a dosage far in excess of that indicated in the British Pharmacopœia, and to give three large doses at six-hourly intervals, and then no more for a time.[1] He claimed to be within the limits of safety in cases where there are no contra-indications to a full digitalis effect, and at the same time to obtain this effect much more rapidly than by the current method of administering this drug. Since the original communication of Eggleston several papers have appeared on this subject, and these have recently been reviewed by him.[2] In this country Eggleston's method has been advocated by Prof. F. R. Fraser,[3] who used it in cases of severe heart failure.

In the following observations the effect of large doses of digitalis has been studied with a view to obtaining information of its pharmacological effect upon the heart-rate, the excretion of urine, and the production of vomiting in cases of auricular fibrillation without obvious failure. The patients were under the care of Dr. John Parkinson in the cardiac wards of the Ministry of Pensions Hospital, Orpington. They were middle-aged males with mitral stenosis and auricular fibrillation. All were dyspnœic on exertion, and some also complained of pains about the left breast. None were actually in a state of failure at the time of observation; they were able to walk about without distress, there was no dyspnœa when at rest, no œdema of the feet, and no enlargement of the liver. Some gave a history of occasional and slight swelling of the feet, and two of them had slight enlargement of the liver on admission.

Method of Observation.

If the patient was under the influence of digitalis on admission, he remained without medicine for at least 14 days. At the end of this period his pulse was usually smaller and more rapid. He was then confined to bed, and the apex-beat was repeatedly counted with stethoscope and charted. The urine was measured six-hourly, and the patient was observed in this way for three to four days before any drug was administered. On the morning of the day of administration he was again examined, and the absence of signs of failure confirmed. One or one and a half drachms of a standardised tincture of digitalis was then administered; six hours later the second dose—1 drachm—was given, and six hours later still the third and last dose, another drachm. The apex-beat was frequently counted and the urine measured six-hourly as before. The observations were continued in the same way for five days subsequent to the day of administration. The whole of this procedure was repeated after the lapse of a fortnight so as to furnish a second and controlling experiment.

---

[9] The apparatus is made by Siebe Gorman, Ltd., 187, Westminster Bridge-road, S.E.

[10] A special order should be given for these tropical standard tubes.

5	28	(*a*)	66	63	− 3	32	44	41
6	40	(*a*)	100	91	− 9	44	32	50
		(*b*)	100	76	−24	53	36	41
7	31	(*a*)	92	90	− 2	52	33	32
		(*b*)	140	115	−25	68	64	92
	Average		102	92	−10	56·5	52	53·4

Results in seven cases of auricular fibrillation free from failure. (*a*), (*b*), and (*c*) indicate separate experiments. The heart-rate is reduced on the day of administration in five out of seven cases; the urinary output is unaffected.

Results.

Effect on Heart-rate.—The heart-rate was in most cases affected to some extent on the evening of the day of administration, about 12 hours after the first dose had been given, and the average fall in rate by this time was ten beats per minute. This fall was maintained the next morning, and later on in that day a further fall of ten beats per minute occurred, though no more digitalis had been given. The quality of the pulse was much improved, the volume being larger. In a few cases coupled beats appeared temporarily. This control of rate, however, was not very stable, as counts taken after meals or after slight exertion or excitement nearly always showed that the pulse had risen towards its original rate. Very often, also, there was a relapse lasting for a few hours without any apparent cause. The total duration of the effect was from four to 14 days.

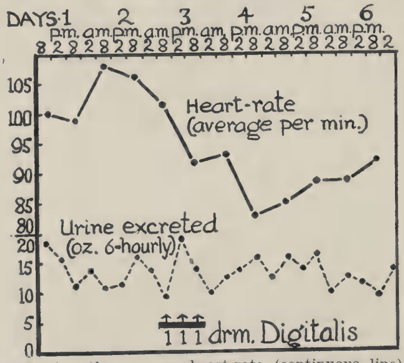

Chart showing the average heart-rate (continuous line) and amount of urine excreted (interrupted line) before and after digitalis.

Effect on Urinary Output.—Digitalis had no definite diuretic effect on any case; this observation confirms the general view that digitalis exerts little or no diuretic effect (even in large doses) unless œdema, obvious or masked, is present. The chart does seem to indicate an increase, amounting to 4–6 oz. during the six hours following the administration of the first dose of digitalis, but there was no increase in the total daily amount, either on the same or on the following day.

Effect on Symptoms and General Condition.—The patients all felt better and said that they had less palpitation. As all signs of failure were absent in the cases observed, there was no opportunity of judging the effects of digitalis on this condition.

Absence of Vomiting.—Apart from occasional coupling of the pulse in two cases there were never any indications of overdosage. Nausea and vomiting were never seen—a fact of special interest, tending to show that the vomiting which sometimes occurs early in the administration of digitalis in heart failure depends far more upon the failure of the heart than upon any irritant effect of this drug on the stomach.

Clinical and Laboratory Notes.

A CASE OF FIBROMYOMA OF THE STOMACH.

BY J. E. G. CALVERLEY, C.M.G., M.D., B.S. LOND.

THE following case is of interest and merits record.

A married woman, aged 50, was suddenly attacked with acute epigastric pain and vomiting. Dr. P. S. Mandy, under whose care the patient had been 15 months ago for severe hæmatemesis, sent her to the Royal Victoria Hospital, Folkestone, for a "leaking gastric ulcer."

On admission to hospital all symptoms had subsided, and the patient was quite comfortable, and in a short time was on full diet. On the fifth day after her discharge there was a recurrence of the acute symptoms, but on readmission all symptoms had subsided. There was no tenderness in the epigastric area; but on one examination a sense of fullness was perceptible over the right rectus (Dr. Mandy had felt a definite tumour). A test-meal, examined by Dr. R. E. Bamford, the house surgeon, showed slight hyperacidity. The history suggested gall-bladder trouble, and an exploratory laparotomy was advised.

Before operation was performed, it was thought an X ray might throw some light on the condition, and this completely altered the diagnosis of gall-bladder. Colonel C. H. L. Palk, radiologist to the hospital, reported:—

> "The lower border of stomach reached several inches below the umbilicus, peristalsis poor, body of stomach appeared as two large areas connected by a narrow channel; there was no obstruction, although some barium was held up in the upper part; a good deal had passed on into the lower area. The condition is suggestive of chronic ulcer."

Operation.—The pyloric end of the stomach was filled with a growth, the size of a Tangerine orange, which on slight manipulation was released from this part of the stomach, and could be moved in all directions. The growth was removed by a partial gastrectomy.

The sudden onset of pain and vomiting was, no doubt, due to obstruction of the pylorus by the tumour, and if an examination had been made during one of the attacks the tumour would have been detected by palpation. The growth was rounded in shape, and partially covered with mucous membrane, which at one spot was ulcerated. The free surface was dimpled, the size of a small thimble. On section the tumour consisted of two encapsuled growths, one on each side of the dimple.

The report of the Clinical Research Association was as follows:—

> "The section shows a fibromyoma arising in the upper layers of the muscular coat. It is little removed from a fibrosarcoma in appearance, and some pathologists might give it that name, but we think it is probably an innocent growth. The condition is uncommon."

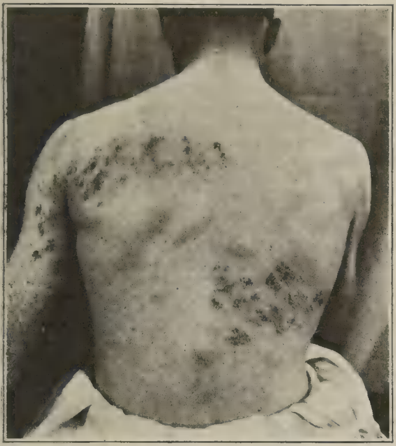
Folkestone.

A CASE OF BILATERAL HERPES ZOSTER.

BY E. R. C. WALKER, B.A. CAMB., M.B., CH.B. EDIN.,
RESIDENT PHYSICIAN, THE ROYAL INFIRMARY, EDINBURGH.

IN the following case the patient could not recall any previous illnesses, and did not remember being in contact with any case of herpes zoster or of chicken-pox.

He was a general labourer, aged 29, of Irish nationality. For about two months before the onset of acute pain he had occasionally experienced a tingling sensation on the upper part of his chest on both sides. About a fortnight before the appearance of the rash he had a stabbing pain about two inches above the left nipple. Ten days later a similar pain developed on the right side at a somewhat lower level. Two days later the rash appeared on both sides. The patient thought it appeared first on the left side, but was not certain. The distribution was as follows: Right side: from ninth, tenth, and eleventh dorsal vertebræ spreading round the chest to midway between the umbilicus and ensiform cartilage in front. Left side: from fourth, fifth, and sixth dorsal vertebræ spreading round underneath the shoulder, above the nipple to fourth and fifth costal cartilages in front, and also down posterior fold of axilla and back of arm.



Showing distribution of lesions on the back after the vesicles had broken down. The photograph was taken by Dr. W. D. Small.

Condition on Admission.—When, on Feb. 2nd, 1924, he was admitted to hospital, seven days after the appearance of the rash, the temperature was 98·2°F., respirations 24, pulse 120. There was a slight rise of temperature in the evening, but this subsided during the night, as did also the respirations and pulse. Wassermann reaction was negative. Urine normal. Bowels slightly constipated.

He made a complete and rapid recovery.

The unusually long history may perhaps be due to the patient's nationality. He was somewhat vague as to facts, and his native courtesy made him very willing to oblige in the matter of remembering early symptoms. He was, however, quite definite about the pain above the nipple a fortnight before the appearance of the rash.

I have to thank my chief, Prof. Jonathan Meakins, for leave to publish the case.

KENT COUNTY OPHTHALMIC HOSPITAL, MAIDSTONE. The annual report of this institution stated that the accounts were satisfactory, but owing to the transition state of the hospital, due to building and rebuilding operations, it was difficult to make any comparison with past years. The total sum realised by the Extension Fund Appeal amounted to over £15,000. The board expressed its deep gratitude to Mr. Wheler Bennett for his handsome contribution of £10,000 to the hospital. The importance of the Weekly Subscribers' Fund was shown by the fact that four years ago this fund amounted to £192 and had now increased to £7925. There were at the moment 206 cases awaiting admission.

Medical Societies.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held in Liverpool on March 14th, with Dr. A. DONALD, the President, in the chair.

DISCUSSION ON PRIMARY PULMONARY THROMBOSIS.

The discussion on the paper read by Prof. E. Glynn,[1] postponed from the meeting held on Jan. 18th, was opened by Prof. BLAIR BELL. He said that to gynæcologists the question of primary pulmonary thrombosis was of special interest, as in all gynæcological clinics throughout the world this disaster had occurred with greater frequency than in the clinics of the general surgeons. Prof. Glynn would, however, be the first to disclaim any suggestion that the idea of primary pulmonary thrombosis was a new one. It had frequently been discussed during the last 50 years, during which time there had been a considerable division of opinion not only as to whether primary thrombosis in the pulmonary artery was commoner than embolus of the vessel, but also concerning the relation of thrombosis in the systemic veins to clots in the pulmonary vessels, and, moreover, whether clotting in the pulmonary artery was centripetal or the reverse. Nevertheless, Prof. Glynn's name would always be associated with the pathology of the subject because he had based his views on strict pathological investigation, a method not adopted by the earlier writers. Prof. Blair Bell thought that the main pathological contentions submitted by Prof. Glynn could hardly be controverted. Prof. Glynn stated that he had performed 35 consecutive autopsies on cases of pulmonary embolus and thrombosis; and in 30 (85 per cent.) of these he had found that the fatal lesion was primary pulmonary thrombosis. He adduced as evidence of primary thrombosis not only the presence of blood-clots, which might be found in all lobes of both lungs, but also proof that they were of ante-mortem formation, for age changes, such as deposition of blood-pigment, were demonstrated in nearly all, and commencing organisation was found in the clot in one-third of the specimens—conditions that could not possibly have developed in the few minutes generally supervening between the onset of the lethal seizure and death. The question of pulmonary embolus did not require special consideration, for the cause and mechanism were easily understood. Moreover, embolism was comparatively rare. The discussion of Prof. Glynn's paper really centred on the problem of the causes and prevention of primary pulmonary thrombosis, and it was probable that the greater frequency of this condition after gynæcological operations was attributable to two causes: (*a*) injury to large veins; (*b*) proximity of large vessels to septic foci. With regard to the first, injuries might be produced in several ways, the chief of which were the temporary application of compression forceps to big vessels like the ovarian, and the stripping free of large veins from the surrounding tissues, in which circumstances actual clotting or pre-clotting changes might more readily be produced in the blood contained within the lumen of the vein. The proximity of large vessels to septic foci was no less important. The proximity of large vessels to a septic area was conducive to changes in the bloodstream by the passage of toxins or organisms through the vessel walls. If the sepsis was severe actual thrombosis might occur in the pelvic veins, in which case a pulmonary embolus was a contingency to be remembered and avoided by suitable measures, such as rest. If the sepsis were mild, local thrombosis did not occur, but the toxins which reached the bloodstream were predisposing factors of pulmonary thrombosis.

---

[1] THE LANCET, Feb. 23rd, 1924, p. 390.

Prof. Blair Bell next directed attention to the numerous other predisposing or determining factors of primary pulmonary thrombosis. These were classified in the following groups:—

1. *Abnormalities in the Blood before Operation.*—There was evidence to show that bacterial toxæmias, toxæmias due to malignant disease, and anæmia from loss of blood might all, in one way or another, lead to conditions in the blood favouring clotting. In addition, actual loss of water from the tissues of the body by excessive pre-operative purging must be considered a definite predisposing cause.

2. *Abnormalities in the Blood after Operation.*—After operation the changes in the blood that predisposed to clotting were due to loss of fluid from the tissues and the effects of anæsthesia. The latter produced in the blood changes that favoured intravascular clotting. Many years ago Prof. Blair Bell had found that in vitro chloroform produced hæmolysis much more readily than ether, and he had no reason to doubt that the same might occur in vivo. Acidosis also, which often supervened on anæsthesia, was a state favouring clotting of blood. Then, again, as Prof. Glynn had said, deficient oxygenation, the result of inactivity during convalescence, was a factor of the greatest moment.

3. *Abnormalities in the Rate and Force of the Flow of Blood after Operation.*—During convalescence, with the patient bedridden, all mental and physical incitements to a rapid flow of blood, an increase in the blood pressure, and a high degree of oxygenation of the blood were reduced to a minimum. How important as determining factors in regard to intravascular clotting the resulting alterations might be would have been realised from Prof. Glynn's remarks about the statistics of Prof. Blair Bell's own cases. Nevertheless, an endeavour had been made to eliminate as far as possible *all* predisposing and determining causes, for in regard to intravascular clotting absolute safety could only be obtained by the abolition of all possible influences, and not only of one or two. The various procedures, many in general use to-day, which in one way or another assisted in the avoidance of the terrible catastrophe were, therefore, summarised.

Pre-operative Precautions.—In cases, especially of fibromyomata, in which the patient was very anæmic, blood transfusion should be practised immediately prior to operation. Pre-operative purging and starvation had almost disappeared from surgical practice, for it was quite unnecessary and robbed the patient of fluid from the tissues. In certain cases in which operations were planned in connexion with malignant disease blood transfusion might greatly improve the state of the patient's blood. In septic cases operation should be delayed, if there was no danger to life, until some immunity in the patient had been established.

Operative Methods.—In connexion with the operation itself, care should be taken as far as possible to avoid stripping bare the great veins on the wall of the pelvis. Clamps should not be placed on large vessels, such as ovarian, prior to ligation; they should be tied cleanly, and then divided. This was specially important in hysterectomy for fibromyomata. In dealing with torsion of the pedicle of an ovarian tumour, in which thrombosis had already occurred, the ovarian vessels should be ligated as high as possible, and not merely at the site of the twisted pedicle. Septic areas in which organisms were alive should be drained; it was a wise procedure to drain all pelvic abscesses not enclosed in the uterus, tubes, or ovaries, which could be removed. Loss of fluid was prevented by careful hæmostasis, and by avoidance of the undue exposure of the peritoneal surface.

Post-operative Care.—With regard to post-operative measures designed to lessen the risk of pulmonary thrombosis, a few only could be mentioned. Loss of fluid, which was to some extent unavoidable during an abdominal operation, was made good by rectal salines, to which glucose had been added to reduce the condition of acidosis that followed the administration of all anæsthetics, but more especially chloroform which was still used by some. Fluid and food by the mouth should be given soon after operation. Intestinal distension, which impaired the movements of the diaphragm, could be effectually treated by the use of infundibular extract followed by turpentine enemata. The blood pressure could be raised, if necessary, with infundibular extract. Finally, the use of systematic exercises accompanied by deep breathing were of the highest value in the prevention of pulmonary thrombosis. Since the adoption of these in January, 1916, only one patient in the gynæcological wards at the Royal Infirmary and one in private practice had been lost from pulmonary thrombosis. The first, a much blanched patient with organic heart disease, died ten days after hysterectomy for fibromyoma. The sister in charge decided, on her own initiative, that the patient was not strong enough to practise movements. The other patient died on the fifth day after operation, and there was some doubt whether she also was not considered by the sister in charge too ill to perform the exercises—in fact, it was almost certain that she did not do them. Naturally, in the presence of thrombosis in the pelvic and femoral veins exercises should not be practised lest emboli be detached, but the patient should indulge in deep breathing.

From what had been said it would be realised that modern surgical practice included many, if not most, of the preventive methods emphasised, and this may have accounted for the fact that death from pulmonary thrombosis was not so common as formerly when patients were purged, chloroformed, and subsequently starved. Nevertheless, the statistics of Prof. Glynn showed that the exercises first described in detail by Prof. Blair Bell in the third edition of his "Principles of Gynæcology" (1919), and employed since January, 1916, had reduced the gynæcological wards at the Royal Infirmary from the head of the list in regard to both the number and the percentages of deaths from pulmonary thrombosis to the bottom. Methods that had effected such an improvement over a period of eight years could not be lightly criticised.

Prof. H. **BRIGGS** (Liverpool) asked when physical exercises should begin and whether the primary pulmonary thrombosis was consequential on a local lung infection. These surprises had not yet been fully explained by the general pathologists.

Mr. K. W. **MONSARRAT** (Liverpool) said that he considered that pulmonary embolism and primary pulmonary thrombosis should be considered separately. He thought that pulmonary embolism was usually due to the detachment of clot in wounds not sterile. With regard to pulmonary thrombosis, he considered an explanation had not yet been given of the tendency to the formation of the clot in the pulmonary artery. He considered that it was probably related to a variety of conditions in the lung which tended to chronic stasis in the pulmonary circulation, as, for example, post-anæsthetic bronchitis. He considered that ammonium carbonate was of some value as a prophylactic.

Miss F. **IVENS** (Liverpool) mentioned that she had had five cases of sudden death in a series of 2500 cases of abdominal section. Sudden death occurred when all was apparently doing well. In one case of death on the eighth day the post-mortem revealed only a much enlarged thymus. In the second, a robust young lady of 25, with a gangrenous appendix, death occurred as she stepped out of bed on the fourteenth day. In the third, an elderly lady with prolapse, two small fibroids, and a chronic appendix, death occurred suddenly on the ninth evening after operation. In the fourth, an anæmic woman of 37, with uterine fibrosis and infected cervix, death occurred nine days after a panhysterectomy. In all these cases the temperature chart and pulse-rate were normal, but sepsis could not be excluded. Two were private cases and post-mortems were unobtainable. In the fifth, a married woman of 30, a right ovarian tarry cyst had been removed. A subnormal temperature was noted on the seventh day, with normal pulse. On the ninth, in the early morning after an action of the bowels, intense pain in the back occurred, and the patient became livid with rapid thready pulse. A violet coloration appeared over the abdomen and thorax, and death took place in four hours, consciousness persisting almost to the end. Miss Ivens thought it possible that in this case thrombosis had spread up from the ovarian veins, induced perhaps by toxins absorbed from the ruptured tarry cyst. The bacteriological findings were negative, but no post-mortem could be made. Miss Ivens stated that in none of her cases had exercises or massage been advised. Prophylactically she attached more importance to an aseptic technique, to the avoidance of bruising of the tissues, and to the dilution and diminution of toxins, whether bacterial or the products of tissue death which tended to cause vascular degeneration.

Mr. **FRANK JEANS** (Liverpool), speaking from the point of view of the general surgeon, said that two factors were important in the production of the condition: (*a*) Slight (not severe) sepsis. He had known pulmonary thrombosis to occur after a breast operation in which a serous effusion had been aspirated on the eighth day and proved sterile on culture—a severe test of asepsis—but one which did not preclude a minute infection. (*b*) Lack of movement on the part of the patient. His impression was that the condition always occurred in the case of the placid patient who was as good as gold and always did as she was told. The patients who got excited and waved their arms and got out of bed never got thrombosis. For this reason he favoured exercise and agreed with Prof. Blair Bell.

Some Theories Criticised.

Mr. **P. R. WRIGLEY** (Manchester) said that his personal experience of this condition was not extensive. In common with other surgeons who had been operating for a number of years he had had a few unexpected and sudden deaths following operation which had been attributed to pulmonary embolism, but for various reasons post-mortem examination had not been possible. Thirteen years ago he operated on a middle-aged woman for extensive varicose veins in the leg, a case which nowadays he would refuse to treat by operation. A few hours after the operation she sat up in bed and became very dyspnœic and died within a few minutes. This he regarded at the time, and still believed to be, a pulmonary embolism. He had met with several other cases in which on about the tenth day following laparotomy the patient had suddenly complained of pain in the chest with great difficulty in breathing followed by hæmoptysis. The symptoms had persisted for a few days, gradually lessening and finally disappearing. These symptoms he believed to be due to thrombosis in the systemic circulation resulting in the minute emboli in the lungs. His house surgeon at the Manchester Royal Infirmary had taken considerable pains to investigate post-mortem records of the Infirmary for the past five years with the following result: During that period there were nine patients who died after operation, and in each case death was attributed to pulmonary embolism. Full details of the clinical features of these cases were not available, but in all of them the operation wound was stated to be nearly healed, so that some days at least must have elapsed between the day of operation and death. In six of these cases the post-mortem revealed thrombosis either of the main pulmonary artery or of one or both of its branches. In the other three cases post-mortem examination showed acute dilatation of the heart and in no case was there an embolism, which bore out Prof. Glynn's statement that primary thrombosis of the pulmonary artery was much more common than embolism. It had been suggested that pulmonary embolism and thrombosis were due to two chief factors—mild sepsis and pulmonary stasis. If mild sepsis was an important factor; why was it more common to get thrombosis or embolism after operations on the pelvis and abdomen and so rarely after operations on the head, neck, and arms, unless this sepsis was due to some organism which normally inhabited only the abdomen, such as the *Bacillus coli?* If due to pulmonary stasis, why did it not more frequently follow operation such as radical amputation of the breast, where one side of the chest must have its movements impaired? On the other hand, after abdominal operations one would expect thoracic breathing to be much exaggerated. He thought there must be many other factors at work as well as these two. He had never ordered routine exercises for patients, but had encouraged them to move and to change their position from the day of the operation with the idea of preventing bronchitis and pneumonia. Prof. Blair Bell had suggested that one predisposing cause might be stripping of large veins in the pelvis, but if this was the case, why did we not more frequently meet with it after operations for removal of malignant glands from the neck and the axilla where the large venous trunks were dissected free from their sheath for a distance of some inches?

Secondary Anæmia as a Factor.

Dr. **FLETCHER SHAW** said he spoke merely to mention one factor in the production of thrombosis which previous speakers had overlooked—viz., anæmia from long-continued hæmorrhage. In his own private practice he had had three cases of sudden death attributed to embolism or thrombosis, all following hysterectomy for fibroids. Two of these occurred within a few weeks of each other and the shock had caused him to investigate the matter deeply. He found in two years he had performed hysterectomy for fibroids on 135 patients and five of these were noted as suffering so severely from the effect of hæmorrhage that they were kept under treatment for some time before operation was undertaken. Of these five anæmic patients, three died, two from embolism or thrombosis and one from heart failure, while amongst the other 130 patients there was only one death and that from acute nephritis, which probably had nothing to do with the operation. He thought this profound anæmia before operation should be emphasised as a contributory factor in the production of thrombosis.

The **PRESIDENT** remarked that he was in full agreement with Dr. Fletcher Shaw in attributing great importance to profound anæmia as a contributory cause of thrombosis, and was surprised that so little notice had been taken of this in the remarks of previous speakers. After a careful study of the records of 830 abdominal operations in his nursing home, he had found that three patients had died as the result of thrombosis or embolus. In each of these cases the operation was for a large fibroid tumour, and all the patients were profoundly anæmic. He thought that in every case of thrombosis there was some infection or toxæmia, and yet the curious fact remained that thrombosis seemed rarely to occur in cases of acute pelvic abscess. He had never seen it following operation for pyosalpinx or abscess of the ovary. The organism must be of a type which favoured clotting of the blood. He thought that in most of these very anæmic patients with fibroid tumours there was a certain amount of toxæmia. The most important point in the prevention of these cases was the most scrupulous, and even exaggerated, attention to aseptic technique, in all tumours associated with much hæmorrhage. He felt sure that the cases were not nearly so common in recent years as they had been. Blood stasis might have some effect, but it only played quite a secondary part.

Sepsis as a Factor.

Dr. **MORRIS J. COHEN** believed that sepsis was the main factor in the causation of pulmonary thrombosis. In 22 cases investigated at the Thompson Yates Laboratories, 11 showed definite sepsis at site of operation; in 11 cases where weight of spleen was noted the average was 7 oz. (cf. normal 4 to 5 oz.).

In 18 cases bacteria were demonstrated in systemic or pulmonary clots or in the lungs. In some they were found in all three places. In 11 of these cases streptococci were prominent. Pre-existing lung lesions such as emphysema, recent or old pleurisy, quiescent tubercle were demonstrated in 16 cases. The temperature charts in all cases showed abnormalities, although in several the temperature was but slightly raised. The reason why thrombosis is commoner in the pulmonary than in the other arteries appears to be the fact that although the pulmonary artery is such by name and structure, yet it functions as a vein. The blood it conveys is of a more venous character than in any vein in the body: it is rich in carbon dioxide and in septic products and products of disintegrating tumours if sepsis or neoplasm be present, and it is also rich in kinase if thrombo-kinase be liberated in the tissues. All these are potent factors in the formation of a thrombus.

GLASGOW SOUTHERN MEDICAL SOCIETY.

A MEETING of this Society was held on March 13th, with Dr. D. G. **CARMICHAEL** in the chair, when Mr. W. A. **SEWELL** read a paper on

Intussusception.

He outlined the pathological features of the condition, and its age and sex incidence. With regard to the mechanism of production of intussusception, he did not agree that there was usually some antecedent disturbance of the bowels; in his series of 31 cases, diarrhœa was present in only one. This was in agreement with the observation by Perrin and Lindsay that no case of intussusception was admitted to the London Hospital during an epidemic of diarrhœa which occurred in London in September, 1911; further, he had been informed by Dr. Leonard Findlay that intussusception had never developed in any of the many hundred cases of gastro-enteritis treated by the latter in the Royal Hospital for Sick Children, Glasgow. Occasionally cases of gastro-enteritis developed ileo-colitis, with blood and mucus in the stool; but in such vomiting was a rare symptom.

There were several theories regarding the cause of the invagination. (1) Presence of a polypus or neoplasm. This was very rare in the infant, although occasionally a swollen Peyer's patch might function as a sessile polyp and form the apex of an invagination. (2) While a long and loose mesentery might facilitate the formation of an intussusception, it was not the cause; further, such a condition of the mesentery was frequently found in adults, in whom intussusception was extremely rare. (3) Perrin and Lindsay had advanced as the determining factor the mass of lymphoid tissue situated around the terminal inch of the ileum. This lymphatic aggregation was most developed in the young child, and became progressively less with age. When it became inflamed and swollen it was treated by the gut as a foreign body, and might become the starting point of an intussusception. The greater liability of boys to infantile ailments, and the fact that the amount of lymphoid tissue in the body varied directly with the size of the child, might explain the preponderance of males in cases of intussusception.

The congestion and swelling of this lymphoid tissue was generally ascribed to changes in feeding during the early months of life. Mr. Sewell, however, felt that more importance should be attached to the appendix as a contributory factor in causing inflammatory changes in the lymphatic tissue of the ileum. In spite of the fact that acute appendicitis was very rare in the infant, he had been struck by the frequency with which lesions of a chronic type were noted in this organ during operations for intussusception. The appendix might be kinked, adherent, or ecchymosed; and while it might sometimes be difficult to exclude operative trauma in certain types of cases, he felt that his view was supported by the number of cases of vague abdominal troubles in children which were completely relieved by the removal of an appendix which showed no notable macroscopic or microscopic deviation from the normal.

With regard to diagnosis, Mr. Sewell thought that when a history of screaming, vomiting, and blood and mucus from the rectum was elicited, no time should be lost in sending the child to hospital for observation. An anæsthetic should be given, and the abdomen carefully palpated for the typical tumour, and rectal examination should never be omitted.

Treatment resolved itself into laparotomy and reduction at the earliest possible moment. A point of importance was the marked shock which frequently followed the reduction of the invagination; he had found that the application to the bowel of large swabs soaked in saline solution at a temperature of 105° F. did much to minimise this. Where the condition of the child warranted a slightly longer operation, he always performed appendicectomy, and he always closed the abdominal wound in layers.

In his series of 31 cases he had lost six; this figure included a case which recovered from the primary operation, but died after a secondary operation for ventral hernia. Resection had been necessary in four cases; in one the patient, an infant of three months, had been ill for 72 hours, and the gut was gangrenous; this case died. The remaining three cases—in children of 10 years, 2 months, and 3 months—recovered.

Prof. **JOHN GRAHAM** mentioned a case in which the invagination was due to a piece of paper swallowed by the child, and Mr. **ROBERT TENNENT** described a case of Henoch's purpura, where a hæmorrhage in the bowel wall had been the starting point of an intussusception.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on April 3rd, Dr. **ELIOT CURWEN**, the President, being in the chair.

Dr. **DONALD HALL** read a paper on

Electrocardiographic Records.

Lantern slides were shown of normal and abnormal electrocardiograms, the latter including various forms of premature beats, sino-auricular block, right and left-sided preponderances, auricular flutter, and auricular fibrillation. Diagrams were also shown upon the screen of the apparatus and of the anatomical relationships of the conducting apparatus within the heart. He said that this method of investigation was particularly useful in analysing accurately the different types of irregularity of rhythm, and in determining whether or not abnormalities of rate were caused in a rapid heart by an ectopic focus of stimulation, or in a slow heart by some degree of heart-block. The ventricular complexes gave information as to the state of the myocardium, which was not to be obtained by ordinary clinical methods. Electrocardiographic records gave information as to diagnosis, prognosis, and treatment, and from the last standpoint especially as to which cases were or were not likely to be improved by the use of digitalis. Too often in arrhythmia, or in tachycardia, digitalis was employed when its exhibition was useless, if not indeed actually harmful. With the precise knowledge afforded by an electrocardiographic record of the case this error could be avoided.

The **PRESIDENT**, Dr. H. **GERVIS**, Dr. L. A. **PARRY**, Dr. E. F. **MAYNARD**, and Dr. H. F. **SEYMOUR** discussed the paper.

Dr. H. M. **GALT** showed microscopical slides of Normal Heart Muscle; Fatty Degeneration of Heart Muscle; Fatty Infiltration of Heart Muscle; and a Section of Heart showing Fibroid Change.

Reviews and Notices of Books.

Canned Foods in Relation to Health.

By William G. Savage, B.Sc., M.D. Lond., County Medical Officer of Health, Somerset. Cambridge University Press. 1923. Pp. 146. 8*s.* 6*d.*

This book, which consists of the Milroy lectures for 1923, slightly amplified, comes as an interesting sequel to the work on food poisoning and food infections by the same author published in 1920. Dr. Savage shows how immensely this industry has grown during the war, so that canned foods have ceased to be a subsidiary means of supply and must now be regarded as an essential source of food. Though the canning industry is small in this country it is important in the United States and the overseas Dominions. Thus the U.S.A. census of 1914 showed 4220 canning establishments in that country, with 88,069 persons engaged. The interesting suggestion is put forward that a great increase of the canned fish industry would be possible in this country by means of a floating cannery to follow the abundance of fish as it moves past the various centres on the British coast. Dr. Savage has examined various methods of manufacture, and pays a high tribute to the work done by the National Canners Association (U.S.A.) in the improvement of the food products of its members. He also shows that the control exercised over canned foods at the port of entry is not satisfactory, and that better and more uniform methods are needed for dealing with the contents of rejected tins. These are now often wasted, but means might be devised for their legitimate use for various purposes. Dr. Savage urges that the date of preparation should be stamped on all canned foods, and, further, that there should be some code mark, disclosed to the Ministry of Health, whereby the tin could be traced back to the actual canning factory. As regards one variety of canned food—namely, condensed machine-skimmed milk—Dr. Savage sees no need for it, and thinks its manufacture in or importation into this country should be prohibited.

The possibility of the causation of disease by canned foods has been much discussed. Dr. Savage's conclusions are that canned foods are safer than fresh foods, but should not be made the main articles of diet, and deficiency in vitamins should be made good from other sources. He shows, further, that there is no evidence in favour of the widespread belief in the great toxicity of decomposing food, and that the danger to health is the risk of the infection of food with the specific bacteria associated with food poisoning. Defects in the preparation and distribution of canned foods are pointed out in his book, and the necessity for persevering efforts to remove them is urged. The author is, however impressed by the great value to the community of this method of food preservation, and convinced that its special risks are for the most part readily guarded against.

Galvanomagnetic and Thermomagnetic Effects.

The Hall and Allied Phenomena. By L. L. Campbell, Ph.D., Professor of Physics, Simmons College, Boston, U.S.A. London: Longmans, Green and Co. Pp. 311. 16*s.*

Hall, an American physicist, discovered that a magnetic field applied at right angles to the direction of an electric current in a conductor has some effect on the equipotential lines—it is quite a small effect and could easily be missed; there are temperature effects associated with this particular experimental arrangement, and these are also minute. This book of over 300 pages is concerned with these two and other associated effects. It must represent a painstaking piece of work, because the literature has had to be gathered from many obscure sources; perhaps this is a case in which the appearance of a book on the subject marks its end rather than its beginning. Doubtless the interpretation of the Hall effect in 1879 was very obscure, though Kelvin had predicted it. When the action was tested in different metals, theories on the subject multiplied, and the author gives quite a number of them in some detail. With the discovery of the electron, some of these theories appeared unnecessarily involved, and at nearly the end of the volume we learn that Hall now interprets the phenomena in terms of the movement of electrons having different functions within the atom.

The book is well produced and has an excellent bibliography.

Tropical Diseases.

Handbuch der Tropenkrankheiten. Third edition. Vol. I. General Editor: Prof. Dr. Carl Mense. Cassel, Leipzig: Johann Ambrosius Barth. 1924. Pp. 713. Gold marks 56.

Those who are familiar with the first edition of Mense which appeared in 1905 will hardly be surprised at the rather pretentious size and remarkable wealth of detail displayed in this—the third—edition. The bulk of the work is much increased by the inclusion of the large bibliography upon which German workers lay so much stress; the addendum dealing with the mosquitoes, for instance, occupies no less than 63 pages, and obviously is by no means complete.

This volume includes only two subjects—Applied Medical Entomology by Adolf Eysell, and Hæmatology by Victor Schilling. The first-named section contains all that is known on the classification, biology, anatomy, and morphology of ticks, insects, fleas, lice, spiders, and linguatulids. The illustrations, partly in line and partly photographic, are excellent. The second portion is an elaboration of a similar work by Schilling in the second edition, which was afterwards published separately in 1914. We have nothing but praise for this exhaustive account of tropical blood work, which is hæmatology in the best sense of the word; four beautiful coloured plates accompany it.

Orthopædic Surgery.

Selected Essays on Orthopædic Surgery from the Writings of Newton Melman Shaffer, M.D., F.A.C.S., Emeritus Professor of Orthopædic Surgery, Cornell University, &c. With Foreword by Dr. Lovett and Dr. Fisher, and Comments by Dr. Cotton, Dr. Nutt, Mr. Blagden, and Mr. Hardon. London and New York: G. P. Putnam's Sons. 1923. With frontispiece, and 14 plates and 51 figures. $5.

Although the papers reprinted in this handsome volume are not new—most of them were written more than 20 years ago—they are of great interest for they contain the fruits of an experience of the surgery of deformity and joint disease which has been unusually extensive. Dr. Shaffer may be considered as the best known living exponent of conservative orthopædics, and one who boldly preached his doctrine at a time when general surgeons were over-inclined to perform extensive operations for tuberculous disease of the joints. In his foreword, Dr. R. Lovett, of Boston, emphasises the importance of Shaffer's work and teaching on tuberculosis of the joints, and of his original contributions to our knowledge of various static deformities of the feet and their correct treatment. His skill in devising and in applying corrective and retentive instruments is of the highest order, and was never better shown than in his treatment of contractions of the foot and shortening of the tendo Achillis. He was one of the first to recognise the importance of the latter condition in the production of certain forms of flat-feet, and the reprint of his original papers on the subject of Non-Deforming Club-foot and on Flat-foot will well repay study at the present time, especially as the author has added to them up-to-date notes which enhance their interest.

The papers on Pott's Disease and Pott's Paralysis embody sound theories and modes of treatment which have hardly been improved upon, except as regards heliotherapy, in the 34 years which have passed since the later of them was written. As much may be said for the essay on Non-interference in Abscess of Chronic Tuberculous Disease of the Joints, of which the conclusions have been amply justified by subsequent experience—they practically form the basis of the most modern treatment in this country and on the continent. The reader must, however, be struck by the fact that not one of the three dozen papers which form this volume is devoted to a study of anterior poliomyelitis or its resultant deformities. This omission cannot have been due to lack of opportunities of study and treatment of this disease. Apparently the subject did not appeal to Dr. Shaffer. Yet he was a pioneer in the movement for the State care of cripples, and for some years superintendent and surgeon in chief of the New York State Hospital for Cripples, where assuredly there were many cases of infantile paralysis among the inmates.

We are, perhaps, justified in assuming that since the title-page of this book informs us that Dr. Shaffer was a medical student as long ago as 1863, he has now retired from active practice, and that in congratulating him on this, his farewell publication, we may wish him many years of enjoyment of his well-earned leisure.

Physiology and Pathology of Bone.

Die Normale und Pathologische Physiologie des Knochens (Experimentelle Orthopädie). By Dr. Walther Müller, Privatdozent für Chirurgie und Orthopädie, Assistent der Chirurg. Univ. Klinik, Marburg (Lahn). Leipzig: Johann Ambrosius Barth. 1924. Pp. 218. Gz.12–14.

A highly specialised book of this description will, of course, only appeal to a certain audience, but to those interested in experimental orthopædics it can be well recommended. Stress is naturally laid on the importance of mechanical factors in connexion with the growth and modification of bones, and these are such as render it often highly unsafe to draw conclusions from animals for application to man. There are 67 figures, mostly radiographs, illustrating abnormalities of bones, variously produced. Bone regeneration and callus formation, rickets, and osteomalacia are fully discussed, and much prominence is given to the influence of the organs of internal secretion on the physiology and pathology of the bones. Altogether it is a very valuable monograph.

Anæsthesia in Dental Surgery.

By T. D. Luke, M.D. Fifth edition. Edited by J. Stuart Ross, M.B. With Chapter on Local and Regional Anæsthesia by Major W. T. Finlayson, L.D.S. Ed. London: William Heinemann. With illustrations. Pp. 238. 10*s.* 6*d.*

Owing to Dr. Luke's death the present edition of this book is Dr. Ross's work, and it more than maintains the standard set by the original work 20 years ago. In a comparatively small volume which is intended primarily to be of practical help to those not constantly engaged in anæsthetics there cannot be much space devoted to the physiology or chemistry of anæsthesia. Nevertheless, Dr. Ross has managed to include the leading facts and to write the book in such a way that its reader is led to understand the principles on which he should work, and to become no mere rule-of-thumb administrator. The chapter on local and regional anæsthesia, contributed by Major Finlayson, gives clear and illustrated directions for carrying out the various injections. The whole book is an admirable guide for those entering upon the administration of anæsthetics in dental cases.

Plant Physiology.

The Physiology of Photosynthesis. By Sir J. C. Bose. London: Longmans Green and Co. 1924. With 60 figures. Pp. 287. 16*s.*

As is customary with this author, this book is not a treatise on the whole problem of photosynthesis, but an account of the investigations made by himself and his associates at the Bose Research Institution in Calcutta. And, as one would expect from his previous work, it is largely devoted to the description and exploitation of self-recording apparatus for measuring plant activities. He has worked with the submerged water-plant *Hydrilla* and recorded the evolution of oxygen. With this as a standard test-object he has investigated the influence of light, temperature, and concentration of CO_2 and of the state of functional activity which he calls "tone." Those with no particular interest in botany will find his apparatus worth considering; they may quite likely extract something from it which would be useful in other work. And the questions of how the various factors which influence photosynthesis influence one another, of limiting factors, and whether the total change is the sum or the product of its constituents are of wide general interest.

The Kingdom of Evils.

Psychiatric Social Work presented in 100 Case Histories, together with a Classification of Social Divisions of Evil. By E. E. Southard, M.D., late Bullard Professor of Neuropathology, Harvard Medical School; and Mary C. Jarrett, Associate Director, Smith College Training School for Social Work. With an Introduction by Richard C. Cabot, M.D., Professor of Social Ethics, Harvard University. London: George Allen and Unwin, Ltd. 1923. Pp. 708. 24*s.*

This book was almost completed before the sudden death of Dr. Southard in 1920. It is a record of a large amount of unselfish work, but the rather indefinite value ascribed to it in the preface and introduction is confirmed by perusal of the case-histories. The psychiatric jargon in the descriptions is unfortunate, and only obscures the issues. Nothing is gained by classifying indiscriminately as *Errores* ignorance, misinformation, and misinterpretation, and as *Vitia* not only vice, but also such bad habits as "laziness about brushing one's teeth." The actual records are for the most part hazy and indefinite, though some of the cases are interesting, and there are useful hints in the book. For example, Case 6, an alcoholic of 20 years' standing, seems to have been much benefited at the Psychopathic Hospital by the meetings of the "men's club" organised by convalescents from alcoholism and one or two social workers. Further details of this mutual work by a group with the same failing would have been interesting.

Throughout the grain is so mixed up with the chaff that few are likely to have the time or patience to attempt its separation, but those who do so will find it worth while.

Pathology.

Lehrbuch der Speziellen Pathologischen Anatomie für Studierende und Aerzte. Seventh and eighth editions. Von Edward Kaufmann, ord. Prof. der Allgemeinen Pathologie u. Path. Anatomie. Göttingen, Berlin, and Leipzig: Gruyter and Co. In two vols. Pp. 1962.

Prof. Kaufmann's well-known text-book on special pathology has been entirely revised and considerably increased in size, and now forms two massive volumes. It is a monument of industry and learning, and is the acknowledged work of reference in this subject. Omissions have been searched for but in vain, and though it is scarcely likely that the author has touched absolute perfection, any lesion not mentioned in his book may safely be looked upon as extraordinarily rare if not actually unique. In spite of its size, the book has been written with due regard for relative values; many subjects have been skilfully condensed, and though a more detailed treatment of certain aspects of disease might be desired, it must be acknowledged that the author's judgment on what should be stressed and what treated more lightly is generally sound. The format is excellent, and we presume that the numbering of the editions means that a later version has replaced an earlier.

COLITIS.

Les Colites. Consultations sur les maladies de l'estomac et de l'intestin (cours de gastro-entérologie de l'Hôpital Beaujon). Par PAUL CARNOT, PAUL HARVIEX, R. FRIEDEL et LARDENNOIS. Paris: J. B. Baillière et Fils. 1923. Pp. 224. Fr.10.

THIS little book contains a series of lectures on the modern methods of gastro-enterologic diagnosis and treatment. A mass of information on the normal functions of the alimentary canal is compressed into small space, and is still in a form easily assimilable by the student. Radioscopic examination, both by screening and by test meals, the chemical and microscopic examination of the fæces, sigmoidoscopic examination, the normal anatomical structure of the intestinal canal are all reviewed in turn. The illustrations are rather crude diagrams, but serve their purpose.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XV. MEDICAL CERTIFICATES IN LUNACY.

BY BEDFORD PIERCE, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE RETREAT, YORK.

"Litera scripta manet."

IT was clearly the intention of Parliament that medical men discharging the responsible duties assigned to them under the Lunacy Acts should be adequately protected. Section 330, Subsection (1) states:—

> ". . . . a person . . . who signs or does any act with a view to sign any report or certificate purporting to be a report or certificate under this Act, or does anything in pursuance of this Act shall not be liable to any civil or criminal proceedings, whether on the ground of want of jurisdiction or on any other ground, if such person has acted in good faith and with reasonable care."

Nothing could be more explicit, but it would appear from a recent judgment that the onus of proving good faith and reasonable care may be thrown upon the physician. Moreover, though it is stated in Subsection (2) of the same Section 330, that a judge may, if so inclined, stay any proceedings against a physician, it does not say that he *must* do so, if he is satisfied that the physician did exercise reasonable care and acted in good faith. The whole position is therefore unsatisfactory, and medical men who do their duty both to their patients and to the community in the most conscientious manner may be placed in an awkward and even serious position.

Position in Need of Amendment.

The present state of affairs is so extraordinary that it is surprising any enlightened community can tolerate it. The public provides and equips at very great expense mental hospitals for the treatment of mental disease but declines to allow anyone to be received voluntarily for treatment. Certificates in lunacy are required before a patient can be admitted, and upon medical men is placed the responsibility of signing these certificates. Yet it would seem they are not effectively safeguarded in the discharge of this public duty. Years afterwards the findings of medical men in a matter that is peculiarly their province may be reviewed and even reversed by a jury of laymen none of whom had even seen the patient at the time.

All are agreed that the law requires amendment; but it may be long before anything is actually done, and in the meantime patients have to be treated and certificates must be signed. The medical profession will not stand aside and permit these patients to suffer and to cause grievous suffering to others merely because it may involve some personal risk to help them under existing legal conditions. In my opinion, however, this risk is for the general practitioner almost negligible if reasonable precautions are taken. Doubtful cases are not so numerous as is assumed, and where there is doubt delay rarely does harm. As a rule, the difficulty is not in the signing of the certificate, but in deciding whether hospital treatment is desirable.

General Principles of Certification.

The chief consideration in the great majority of cases is the welfare of the patient, it being impossible to secure proper treatment at home. Until patients can be received voluntarily into mental hospitals, large numbers of poor persons must be certified, since in no other way can they be treated effectively. The establishment of psychiatric clinics in large centres of population would to an even greater extent reduce the need for certification. In a minority of cases legal detention is demanded in the interests of the public; and here special care is needed, and it is often desirable to see a patient several times before coming to a decision.

For private patients two certificates by independent medical practitioners are required. They must see the patient separately, and one of them should, if possible, be the usual medical attendant of the patient. This provision alone greatly reduces the risk of legal trouble later on. A single certificate, however, suffices for a pauper patient; and here it must be remembered that the inability to meet the cost of treatment frequently results in the patient being classified as a pauper, although but for this the family is self-supporting. One certificate, also when accompanied by a medical certificate of emergency, suffices for the admission of a private patient as a temporary measure under an urgency order.

The Certificate a Legal Document.

The certificate is a legal document, and as such it must be judged by legal and not by medical standards. It gives the evidence which justifies the serious step of depriving a person of his liberty. It consists of two parts, usually printed on the forms provided, and I fear sometimes the full meaning is not fully appreciated. First, it states that the patient is of unsound mind, second, that he is "a proper person to be taken charge of and detained under care and treatment." Then follows the reasons for arriving at this conclusion. It is not sufficient to show that the person is insane; it is also necessary to show that he needs to be taken care of and detained.

Facts Observed at the Time of the Examination.

These facts constitute the essential part of certification, and unless they are adequate the certificate is invalid. But in some cases, although there is no doubt about the insanity of the patient and the need for detention, he may during the examination give plausible accounts of his conduct or may deny the statements made by trustworthy people. Again, a patient may vary in his mental state, being reasonable when the doctor is present and quite otherwise when he has gone. A second and third examination will in such cases usually suffice to elicit the actual facts.

The most difficult cases are those with mild degrees of mania or melancholia. The former may ruin themselves with extravagance or exhibit serious misconduct, whilst the latter sometimes commit suicide before steps are taken to safeguard them. Whatever is done or is left undone will probably be criticised adversely after the event by somebody. On the whole, however, the risks of delay are less serious than those involved in prompt certification. Moreover, in this type of case it will be found almost impossible to describe the condition in terms that will be convincing to anyone who cannot observe the patient for himself.

It is often possible to bring information received from friends up to date by discussing it with the patient. Thus: "He admitted that he stopped a complete stranger in the street yesterday and asked him why he made an offensive remark and that the stranger denied having spoken at all." Again, the patient's manner and mode of reply when reminded of incidents are valuable evidence: "He smiled and appeared unconcerned when I asked him why he struck his mother last Monday." Sometimes the refusal to answer questions is in itself important: "When asked why he refused his food and whether it was true that he thought it poisoned, he made no reply." In many cases it is desirable to tell the patient plainly that the state of his mind is called in question; this not only gives him full opportunity of objecting, but the physician is the better able to form an opinion on the mental state.

The examination of a patient should never be hurried; notes should be made at the time or immediately afterwards. It is important to be certain that the condition observed cannot possibly be due to the effect of sedatives, alcoholic intoxication, febrile delirium, or any purely temporary condition affecting the integrity of the mind. More than 30 years ago, in Scotland, I examined a newly-admitted querulous depressed patient; I had doubts about the insanity but none about a recent pneumothorax which had been overlooked.

Facts Communicated by Others.

These may be entirely omitted; and in many cases the certificate is better without them. Their insertion is necessary when the true meaning of the facts observed by the physician is not clear otherwise.

There are many important facts of which the physician may have no personal knowledge, such as the refusal of food, the existence of faulty habits, acts of violence, and much besides. The presence of delusions often cannot be asserted with confidence without information from others. The patient may declare he is utterly ruined, and if this is given as evidence of insanity it must be accompanied by a statement by a trustworthy informant to the effect that the patient's belief is not justified. The doctor himself is not likely to know the true financial position. The greatest care should also be taken with regard to delusions of infidelity, it being often impossible to ascertain the truth with certainty, and the possibility must be borne in mind that these and delusions of suspicion may have some basis of fact.

A certificate is often strengthened if it can be shown that the patient's manner or conduct has undergone a marked change. The facts observed may perhaps be excused or explained away had they been found in certain other individuals, but when they are opposed to the whole tenor of the patient's former life they are significant. Relatives can give evidence on this point. Nevertheless, a certificate must not rest on information supplied by others, however trustworthy it may be, although such information may be used to great advantage in its support.

The Wording of the Certificate.

It is by no means easy to find appropriate words. The certificate should be terse and to the point, and a long certificate is often a weak one. Nevertheless, economy in words must not leave their meaning in doubt. Many words are almost without value unless amplified or illustrated. Such words, for example, as excited, noisy, depressed, abusive, moody, taciturn, unreasonable, and suspicious may be used to describe conduct which is perfectly normal in certain circumstances. A certificate containing the statement, "He was very noisy and abusive, and called me a damned fool," was returned by the Commissioners with the stereotyped reply, "Will the certifier state some facts more clearly indicating insanity?" (!)

In the endeavour to avoid ambiguity it is undesirable to use technical terms. When they are necessary they must be explained or illustrated. For instance, if the word hallucination or delusion is used, an explicit description of the symptoms should follow. It is not enough to say that the patient suffers from hallucinations of hearing. Particulars should be given, such as, "He told me that he heard the voice of his deceased sister speaking to him last night." In some cases it is almost impossible to word a certificate so as to avoid all conceivable misunderstanding. This difficulty, however, is no excuse for the use of loose or vague expressions which give the impression of haste.

It is a good plan to write a certificate first in draft, and before copying to go through it with the thought that it may one day be produced in court, and perhaps criticised unkindly by an advocate who wishes to distort its meaning.

Other Important Points.

Attendant Circumstances.—Obviously the physician cannot put all the facts on the certificate, and in a difficult case there is no objection to his attaching to it a memorandum giving additional particulars. It should be remembered, however, that all these details have to be copied in the mental hospital and cause much extra work. In most cases it suffices to make precise notes of the attendant circumstances and pigeon-hole them carefully. Such notes are invaluable if difficulty subsequently arises. In court it seems to be assumed that a doctor can remember all particulars of a patient examined years ago, and if no records are forthcoming it is quite possible that an adequate certificate may be made to appear weak and incomplete. The admission by the physician under examination that he has forgotten some important fact may create a bad impression.

Dates.—There are three distinct situations to consider: (1) When a patient is received on an urgency order, the medical practitioner signing the certificate must personally examine the patient not more than two clear days[1] before the reception of the patient in the hospital. (2) In the case of a private patient the two medical practitioners must separately examine the patient not more than seven clear days before the date on which the petition is presented to the justice of the peace. (3) In other cases the medical examination must be made not more than seven clear days before the date of the justice's order.

It is obviously unwise to run any risks of the certificate being out of date, which will result in the patient being discharged, and consequently the examination should take place well within the prescribed period.

Minor Details.—Lack of reasonable care may easily be imputed if the certificate is incorrect or incomplete in its minor details. It is astonishing how many certificates fail to describe informants accurately or fail to give their proper addresses. Not a few contain some mistake in dates, or omit to give the full names of the patient. Marginal notes on the certification form give full particulars of what is required, and in quite 10 per cent. of the cases it would appear that they have not been carefully read. Medical men, who are chiefly concerned with the welfare of the patient, are apt to be impatient of legal formalities. But they should remember that, when the liberty of the subject is involved, accuracy in every item is imperative and none of the details required is unimportant. In any case it is unwise to ignore provisions laid down by Act of Parliament.

So far as I am aware the University of Durham is the only examining body that requires every student in his final examination in medicine actually to examine a mental case and sign a certificate in lunacy.

In conclusion, I do not think that the practitioner need have any fear of legal proceedings if he remembers that the certificate is a legal document, if he takes pains in the examination of the patient and in the drafting of the certificate, and if he makes notes at the time of the main circumstances which influenced his judgment, and, of course, preserves the notes.

---

[1] The term "two clear days" is construed so as to allow two entire days to elapse between the examination and the reception of the patient. For instance, in a case of urgency the patient may be examined on a Tuesday and be received in the mental hospital on a Friday.

THE LANCET.

LONDON: SATURDAY, APRIL 12, 1924.

AMBULANCE CASES IN LONDON.

LAST June the PRINCE OF WALES, as President of King Edward's Hospital Fund for London, appointed a Special Committee to inquire and report "on the methods employed for ascertaining where bed accommodation is available at hospitals in the metropolitan and neighbouring areas for accident cases requiring admission, and on the proposal that daily reports of vacant beds should be supplied to the police and ambulance authorities, and to make such consequential recommendations as they may consider desirable." This Committee having heard representative witnesses and interpreted its duties in a liberal manner, has now issued a report of great practical interest. The Committee has been unable to discover any method by which, with the means at their disposal, the hospitals and infirmaries of London can be brought into immediate and effective contact with the urgencies of accident and illness; but it has at least pointed out some of the difficulties that beset this branch of hospital work and how they arise. The demand for inquiry was provoked by two things: street accidents in which undue delay was alleged in the arrival of ambulances after accidents; and urgent cases brought by ambulance to an institution not able to take them in, or not able to retain them for more than immediate treatment. No doubt there was frequent exaggeration in the descriptions of the circumstances—minutes feel like hours in the presence of tragedy; it is, however, beyond dispute that avoidable delay should be avoided and that cases of serious illness or injury should not be transferred from one institution to another in a vague and miserable *tournée* of disappointments. It is equally clear that the conditions of modern street traffic in a London which is crowded, huge, and rapidly extending, are largely responsible for a state of things which cannot be dealt with satisfactorily without drastic and expensive reorganisation. The Committee pointedly observes, "If we were engaged in planning an ideal arrangement for an urban community in which no previous provision existed, a scheme of suitably located casualty clearing stations adequately staffed might be devised, with motor ambulances, summonable by telephone, attached thereto, and equipped with a sufficient supply of casualty and observation beds." Even that would mean much money, but the actual circumstances to be met imply still larger sums. In order to deal satisfactorily with all sudden or accidental emergencies in the London of to-day, there must be large sums spent on providing beds, staffs, and ambulances for that express purpose, without regard to the fact that at times a proportion of such material will not be in use and will seem superfluous.

Although delay in the arrival of ambulances seems to have contributed to the holding of the inquiry, the Committee was not by the terms of its reference concerned with the question of the adequacy and efficiency of ambulance provision. It states, however, in passing that the area within the County of London, with recent and prospective additions to the service, appears to it to be well supplied, but that in the neighbouring areas there would seem to be need for better provision. The Committee had actually to inquire as to cases of inability on the part of the first institution sought to accommodate the patient brought to it for treatment, and as to other cases in which the patient had, before his cure was complete, been transferred elsewhere. This, of course, occurs in many instances in which a voluntary hospital, owing to the case not being suitable for retention in its wards, seeks to pass it on to a Poor-law infirmary which may, or may not, be willing or able to receive it. Poor-law institutions naturally have their limitations and regulations, and are primarily provided by the ratepayers of a defined area for the treatment of patients whose normal residence is within that area. The Committee therefore found itself confronted with a complicated state of things in which voluntary hospitals and Poor-law infirmaries, unsystematically scattered over the metropolis, receive under different regulations or practice cases of accident and illness occurring in streets and public places, generally handled in the first instance by the police controlled by the Home Secretary, and mostly conveyed by a municipal ambulance service. The position is complicated by diversity of practice obtaining in Poor-law infirmaries, by there being more than one ambulance service within the county, and by the police area of London covering portions of Middlesex, Surrey, Kent, Essex, and Hertfordshire outside the area of the County of London. The task of coördinating these services cannot be an easy one, and the question of ways and means for improvement must be prominent in any discussion with regard to it. The Committee is definitely of the opinion that the proposal that daily reports of vacant beds should be supplied to police and ambulance authorities is not practicable, and that even if it were so it would not prove to be of any real service or advantage.

The concrete recommendations of the Committee in the circumstances are to the effect that King Edward's Hospital Fund, in making its annual grants, should take into consideration whether hospitals, which deal with cases of accident or sudden illness occurring in streets or public places, provide a reasonably sufficient number of beds for such cases, and a reasonably sufficient number of beds, or observation beds, attached to the casualty department, in order to avoid, as far as possible, transfer to another institution of any patient whose condition might be prejudiced by such transfer. Here particular notifications to the police and ambulance authorities would be serviceable. They should be provided with lists which would indicate the institutions able to accommodate the cases in question, the lists being made up by the coöperation of the Ministry of Health in the case of Poor-law institutions and of King Edward's Hospital Fund in the case of voluntary hospitals. The intervention of the Minister of Health is considered necessary clearly in order to secure funds where needed, in cases where the Poor-law infirmary might consider the patient not to be entitled to its aid at the expense of the ratepayers who provide the institution; for the Committee advises that in the cases under consideration, including cases transferred, no question should be raised by the infirmary as to the place of residence of the patient, as to where the accident took place, or as to the site of the transferring hospital; in other words, the charge for treatment of such cases should be a common Metropolitan one, and should not fall on the union receiving and treating such patients. A further very proper recommendation is to the effect that no disability should arise out of technical pauperisation through a patient of the class indicated being treated in a Poor-law institution. The recommendations made therefore may be summed up as advising the use side by side of beds in voluntary hospitals and Poor-law infirmaries for the reception of accident cases and cases of illness occurring suddenly in public places, with recognition of the difficulty in present circumstances of keeping vacant at all times beds for the reception of such cases. There is further recognised the fact that the prolonged treatment of all cases brought to a hospital by ambulances is not possible consistently with the hospital rendering the best service possible to the community. Some cases have to be transferred to Poor-law institutions in order to make room for patients who will find their best hope of recovery in the hospital, or whose condition renders them best adapted for the purposes of a hospital where there is a medical school. That transfers are not to be made where the patient is likely to suffer in consequence follows as a matter of course.

The report of the inquiry, in the course of which the closing of wards for lack of funds at some hospitals was mentioned, should go far to convince the public that only want of money prevents the hospitals of London from performing to the full their share in the task of providing for street accidents. To keep vacant beds for accidents which may not occur must risk the withholding of hospital treatment for a person who without it will have no chance of recovery, although his or her condition is not due to accident. It seems clear, therefore, that beds for accidents must be provided specifically and kept vacant for that purpose alone. The hospitals ask, "Who will provide them ?"

◆

ALCOHOL AND LONGEVITY.

In the new edition of the official publication on "Alcohol and its Effect on the Human Organism"[1] each chapter has been subjected to revision, a new chapter on alcohol as a medicine has been added, and the publication can claim to comprise in nearly every particular a dispassionate and judicial summary of the drink problem on its scientific side. It can scarcely claim the remarkable lucidity of exposition of Prof. E. H Starling's book on "The Action of Alcohol on Man," though it is well written; but it purposely avoids appeal to other than scientific considerations; and in its preface, referring to Prof. Starling's discussion concerning the social value of alcohol, the very proper comment is made that these discussions "are at present, and are long likely to be, matters for individual judgment and opinion rather than for scientific decision." In this wider world, the man in the street, the social worker, or the hygienist anxious to remove one of the most serious causes of poverty and sickness as well as of vice and crime, is as much entitled to a hearing as the physiological investigator. The chapter in the new edition likely to be most discussed is that dealing with the influence of alcohol on longevity. Until recently the discussion on this point has turned chiefly on the experience of the United Kingdom Temperance and General Provident Institution. This experience showed that among males insured for whole-life policies 26·4 per cent. fewer deaths occurred among the abstainers than would have taken place had they died at the rate observed in the class of non-abstainers. This was so, although the non-abstainers had a mortality almost identical with that of the average of persons insured in 23 British offices. There are many causes besides alcoholic habits which may have contributed to this difference, and on the whole the matter is fairly summarised in the chapter in question, although everyone may not agree with the cautious decision that "we cannot regard the experience of the office as conclusive," especially in view of the full actuarial details given 20 years ago by Mr. R. M. Moore.[2]

New matter in this chapter embodies a summary of Prof. R. Pearl's contribution to Prof. Starling's book. This gives evidence based on a continuous record of the alcoholic habits of some 2000 persons in Baltimore, who had died after reaching the age of 20 years. These persons were classified into (1) total abstainers throughout life; (2) moderate or occasional drinkers, including persons who might only very occasionally take a single glass of beer or wine; and (3) heavy or steady drinkers, including both drunkards and daily steady drinkers in however moderate amount; and it was found that the mean age at death among male members of group 1 was 60·05 years, of group 2, 61·04 years, and of group 3, 55·37 years. We share the regret expressed in the Medical Research Council's booklet that Prof. Pearl adopted the above method of classification, "which deprives us of nearly all the benefit which we had hoped to derive from his admirable material." No one would argue that an occasional glass of wine or beer would appreciably shorten life. On the other hand, no one doubts that intemperance shortens life. What we really need to know is whether the daily moderate (carefully defined) use of alcohol influences duration of life. As stated in the chapter from which we quote, the real problem is, "are a daily pint or two of beer or a daily bottle of claret, or a few glasses of whisky-and-soda per diem harmful ?" and family histories carefully collected ought to throw light on this question. But at this point doubt is raised as to whether the "material," the statement of which, with less interesting statistical material, fills about one-fourth of Prof. Starling's work is "admirable"; and severe criticism of its value is comprised in a recent article[3] by Prof. Harald Westergaard, the distinguished statistician of Copenhagen, which has reached us. Prof. Westergaard points out that the Baltimore statistics deal only with the persons in the experience collected who had died, and take no account of those still living, thus ignoring the greater part of the total persons at risk in the experience. On this basis Prof. Pearl is obliged to assume that the mean age at death of persons in each of his three groups who have died at ages 20 and over gives a fair basis of comparison between these groups. But, even if on other grounds this method of statement were wise and trustworthy, a preliminary objection to it arises. In view of the steadily increasing temperance propaganda younger men are likely to be total abstainers in larger numbers than older men; hence it follows that, other things being equal, deaths among total abstainers will be at an earlier age than deaths among non-teetotallers. This makes it all the more noteworthy that with such a test the vitality of abstainers should have been greater than that of steady drinkers. The method in itself is, however, essentially unsatisfactory. It is described by Prof. Westergaard as "quite obsolete and misleading." Many years ago an investigation by the same method undertaken by the British Medical Association showed a mean age at death of abstainers of 51 years and of the habitually intemperate of 63 years; and official disclaimers against the obviously illegitimate inference drawn from these figures did not prevent their display in public-house windows as valid evidence that drunkards live longer as well as merrier lives than teetotallers!

[1] Alcohol and its Effect on the Human Organism. New edition, revised by the Medical Research Council. H.M. Stationery Office. 1s.

[2] Journal of the Institute of Actuaries, Nov. 30th, 1903.

[3] Reprinted from the International Review against Tuberculosis, 1924.

The same method was exposed repeatedly by **WILLIAM FARR** in the early reports of the English Registrar-General. It is a method which, by using illustrations, **FARR** reduced to absurdity. The mean age at death, he remarked, is not a factor to be trusted; for were this test accepted—as he wrote in the Fifth Annual Report of the Registrar-General—it would be necessary on behalf of the young but early dying cornets, curates, and barristers "to make them generals, bishops, and judges for the sake of their health." Although the Baltimore figures do not diverge widely from what were probably the actual facts—like the extreme illustrations cited above—confidence cannot be accorded to results thus obtained. The right method of investigation is to observe a certain number of living people during a certain number of years, which can be done retrospectively, the fate of each person whether dead or still alive being set down, and death-rates recorded from which, if desired, the actuarial expectation of life can be calculated. Our knowledge has not been increased by the Baltimore figures, and they lend themselves to misleading quotation. The experience of insurance societies, when fully analysed, points to the superiority of the life-prospects of teetotallers over moderate drinkers, among whom there would admittedly be a small proportion of intemperate persons. This experience should be considered in conjunction with the physiological and pathological facts as to the action of moderate doses of alcohol, given both in the publication of the Medical Research Council and in Prof. **STARLING**'s book, when the conclusion will be justified that abstinence from alcohol is a valuable means for prolongation of life and promotion of efficiency.

THE SIZE OF INFECTIVE VIRUSES.

THE attempts which have been made from time to time to simplify the administration of fever hospitals by one or another form of "bed-isolation" have led to information which is of some interest in connexion with the question of the unidentified (or, at any rate, unseen) agents which cause some of our common infectious diseases. Chicken-pox needs a barrier of the order of the wall of a room, measles spreads easily from bed to bed; in both cases the volatility of the infection is greatest in the first two or three days. Everything else seems fairly safe to manage in a common ward with not too much crowding and a well-trained nursing staff. One thing is certain—that there must be plenty of room. The density of the infectious agent may be assumed to vary inversely with the square of the distance from its source. Under conditions of serious overcrowding, diphtheria, meningitis, and influenza will spread quite freely, whereas under reasonable conditions of space they are by no means highly catching. Apart, however, from this circumstance, the facts suggest several possibilities about the nature of the viruses. It may be that the cause of chicken-pox is viable for a longer time outside the body than that of scarlet fever; of known pathogenic bacteria the gonococcus is an example of how little a complete parasite may be able to tolerate the conditions in the outside world. But other evidence is against this being an important factor, since there are good grounds for believing that the cause of scarlet fever may live outside the body in an infective state for at least several days, and less frequently a prelude to infection than with chicken-pox.

Size of the virus may be an important consideration. It is a striking thing that the two diseases of known ætiology which are caught so frequently by those who work with the bacteria that a practical nuisance arises—Malta fever and tularæmia—are both caused by exceptionally small, though plainly visible, organisms. Rocky Mountain fever and typhus are quite dangerous too, but in both there is a special insect vector as well as a very small organism. From which we get support for the idea that the causes of chicken-pox and measles are also very small—much smaller, that is, than bacteria like the diphtheria bacillus or the meningococcus. In the case of measles, at any rate, there is other evidence that the cause is small or has a small phase in its life-history. The floatability or volatility of particles obviously depends greatly on their size and specific gravity. The latter is presumably not very widely different through the whole series of live organisms. Down to a diameter of about 1μ particles in air behave like pieces of solid matter. The limit of microscopic vision is somewhere about 0·25μ, and a particle as small as 0·1μ has so much surface relative to its mass that its properties are no longer directly in line with those of similar larger bodies. It fails, for example, to obey Stokes's law for falling bodies, which is direct evidence that it would be particularly liable to float about in air even longer than would be expected from its size. It is quite unknown how big the invisible viruses which will pass the pores of a fine porcelain filter really are. Experiment indicates that some of them are no bigger than a molecule of hæmoglobin—an almost incredible conclusion. But if they were ten or a hundred times larger they would still have an exceptional carry through the air. When the viruses are known and measured, it will be interesting to see whether the possibilities of bed-isolation can be calculated in terms of colloidal ballistics.

GLASGOW ROYAL INFIRMARY: THE LISTER WARD.

THE demolition of the old block of the Glasgow Royal Infirmary, of which the Lister Ward forms the ground floor, is proceeding apace, but the lay press of Glasgow continues to pay considerable attention to the whole question of the retention of the fabric. On March 26th the Presbytery of Glasgow passed a motion "strongly protesting against the proposed destruction of the ward, and expressing the hope that it may be possible to retain it as a memorial of Lord Lister and his great work in the infirmary." A similar protest has been made by the employees of at least one large city firm; and protests from interested individuals have been numerous. The level of the adverse criticism shown in these discussions and letters has been very uneven, and in some cases quite different issues have been introduced and discussed. The managers of the infirmary, however, continue to pursue the policy upon which they originally decided, and which was ratified at the annual meeting of subscribers. It has been suggested that their refusal to be influenced by the press and scientific and corporate bodies must have an adverse influence upon the income of the infirmary. We cannot think that this will be so. The routine work of a great infirmary must go on, and to curtail its beneficent activities by wilfully reducing its income would seem to us but a poor way for those who disagree with the managers to show their displeasure.

"Ne quid nimis."

PROVISION FOR DEFECTIVE CHILDREN IN LONDON.

The Education Committee of the London County Council have published a descriptive pamphlet [1] explaining the variety and nature of the provision offered for the education of defective children of all kinds. This provision has steadily increased since the commencement made by the old School Board for blind and deaf children in 1893, and it now covers all forms of disability. Experience has shown that difficulty still arises from the lack of public information on this subject; sometimes children who could benefit fail to attend as early as might be wished owing to their parents and advisers being unaware of the existence of educational facilities other than those of the ordinary elementary school. The special schools also serve as a link in the chain of after-care and medical or surgical supervision. The care committee organisation attached to each school endeavours to ascertain through the hospital almoners the frequency with which the members of the clinical staff wish to see their patients so as to secure their attendance at the prescribed times. Also they arrange that after periods at convalescent homes or residential institutions the children shall resume attendance whenever necessary at their hospital of origin, thus diminishing the change of venue which is often a source of confusion. While in the schools the children are under the supervision of a specialist medical staff who see them from time to time and advise as to return for treatment. In the intervals any child can be seen by a member of the general staff of school doctors. This procedure has the advantage of securing the return for treatment in many cases in which the parents, left to act on their own judgment, might delay longer than is advisable. The curriculum at each type of school has been thought out specially to meet the difficulties of particular defects and to prepare, at the later ages, for some definite occupation; while the after-care committees assist in placing out former pupils and in keeping a general supervision over their welfare up to the age of 18. In the case of the schools for cripple children, conveyance by ambulance from the home to the school and back is arranged and a fully trained hospital nurse is in attendance throughout the school hours. Children are admitted to special schools only on the certificates of medical officers on the staff of the Public Health Department of the L.C.C. who have been recognised by the Board of Education for the purpose, and to whom all information received is transmitted. We understand that Sir William Hamer, school medical officer for London, welcomes the fullest coöperation with hospital staffs and would gladly exchange information with regard to children or receive suggestions for their welfare emanating from the physicians and surgeons under whom they have been treated. An appendix to the pamphlet gives a reference list of the special schools, nearly 200 in number, which form part of the L.C.C. education service.

PARTIAL GASTRECTOMY: A RETURN TO BILLROTH I.

It is becoming increasingly evident that medical science is in danger of over-specialisation; the various branches are developing more and more into watertight compartments, and the student on completing his preliminary studies is apt to regard them with a sigh of relief as a closed book. Anatomy and physiology are forgotten, while surgery is proceeding along the lines of brilliant technical achievements rather than upon the conservation of function. No better example is needed than the surgery of the stomach. In the collected papers of the Mayo Clinic, Vol. XIV.,[1] an extensive section is devoted to the surgery of the stomach, and there are many papers on gastric and duodenal ulcers and carcinoma, which must prove of great value to any surgeon who is confronted with these conditions in his routine work. The history of the treatment of the peptic ulcer is probably more remarkable than that of any other single condition. For many years the discussion has continued, and as time passes the question of the treatment of the peptic ulcer provides an evergreen subject for the programmes of the greater and the lesser medical societies. The surgeon having in any given case persuaded himself and the physician and the patient that active surgery alone holds out any hope of permanent cure, is then confronted with a bewildering variety of methods, the gradual trend of opinion being in favour of certain operations of greater and greater magnitude. The conclusion must be fairly obvious, for the very complexity of the whole subject surely points to dissatisfaction with the results. It is now conceded by the majority of serious surgical investigators that no one method is applicable to ulcers of every type and in every situation. This point of view is admirably dealt with by William J. Mayo in his paper on Radical Operations on the Stomach. There is no gainsaying that many ulcers and many carcinomata of the stomach will demand a partial gastrectomy. It will be remembered that the early cases of this operation were invariably completed by an end-to-end anastomosis of the stomach and duodenum, the pioneers in this work being Pean (1879), Rydygier (1880), and Billroth (1881). The anatomical conditions imposed upon these surgeons the problem of anastomosing a duodenum of small calibre to a much larger stomach. The disparity in size was reduced by stitching up the stomach until an area was left corresponding in size to the cut end of the duodenum. The result was the production of the "fatal suture angle" which in itself was sufficient to cause this operation, which had come to be known as the Billroth I. operation, to fall into disfavour and even into disuse.

Simple gastrojejunostomy, the Polya and Billroth II. methods of partial gastrectomy, are admirable technical achievements and are undoubtedly demanded by certain anatomical and pathological conditions, but it cannot be denied that they result in grievous disturbances of physiological function. The return to the Billroth I. operation is a return—as near as may be—to physiological conditions, and its steady restoration to favour is an indication that the surgical profession as a whole is alive to the evil results of the severe impairment of gastric function. It only remains to prove that the original defects of this operation have been overcome and to appreciate how this result has been achieved. Shoemaker has demonstrated that under modern technique leakage does not occur at the suture angle, and that quite a large extent of the lesser curvature and the pylorus can be removed, at the same time leaving a large area of stomach behind, permitting an end-to-end anastomosis of stomach and duodenum. Mayo emphasises the vital importance of the thorough mobilisation of the lesser curvature, and draws attention to one serious complication—viz., the dropping back of the stomach to the left of the spine—thereby putting an undue strain on the anastomosis, and impeding gastroduodenal drainage. He points out that this may be overcome by fixing the anterior wall of the stomach to the suspensory ligament of the liver in such a way that the anastomosis is firmly anchored to the right of the spine. With attention to such details of technique, Billroth I. has once again become the operation of choice, and has in addition this great point in its favour, that the normal physiological and anatomical conditions are reproduced as nearly as is compatible with the removal of the damaged area. In those cases, however, in which too large a portion of the stomach has to be removed, as in some cases of carcinoma, then the nearest approach to the restoration of physiological conditions is Moynihan's modification of the Polya method.

BROKEN GLASS AS A POISON.

RECENT correspondence in *Municipal Engineering* has voiced the anxiety of its readers in regard to the presence of broken glass in their food, the possibility especially of appendicitis and cancer arising being emphasised. No doubt the frequency of these two diseases affords the reason for their rather arbitrary selection. We are not prepared to deny that broken glass can produce appendicitis, as the multitudinous variety of foreign bodies found in an inflamed appendix includes glass particles, but to suggest broken glass as a common cause of appendicitis lacks foundation entirely. As a cause of cancer broken glass is not worthy of discussion. Judging from this correspondence, however, the use of glass containers for sterilised food is on the increase, and certain results are known to follow. 1. As one manufacturer of jam points out, bubbles of air in the wall of the glass container, especially if close to the internal surface of the jar, may burst, causing flakes of glass to become detached and pass into the food when it is poured hot into such a jar. 2. Glass jars are moulded by machinery, and when the two halves of the mould do not fit tightly together glass is squeezed out into thin plates at the seams. When hot food is poured into such jars, these plates of squeezed-out glass become detached. 3. During the pouring of the hot food into the jars—which are often of inferior glass—the whole container may fly, and the food, instead of being discarded, is strained through sieves which do not prevent the smaller particles from passing through with the food. Regarding the alleged poisonous effects of powdered glass, it is not without historical interest to note that Dr. W. Johns, F.R.S., writing in THE LANCET of Feb. 19th, 1825, recommended the use of pulverised glass as an efficient vermifuge. In his article he stated that he had used this substance for many years on children and adults with uniform success, giving two scruples every day for a week, followed by calomel for children. In the Middle Ages powdered diamonds were used to produce sickness and death, and Benvenuto Cellini in his autobiography records that such an attempt was made on him, but the individual instructed to powder the diamonds substituted another substance so that no ill-effects resulted. Coming to more recent times, in the Baroda case diamond dust was administered with arsenic in sherbet. The effect of swallowed glass depends, of course, upon the size and sharpness of the particles—a large fragment will produce the same symptoms as any other sharp foreign body; the fine particles appear to have very inconstant results. On the one hand, there are authentic records of professional glass-eaters who have practised many years for gain; ultimately, as far as is known, these succumb to the effects of their calling, usually from some form of gastro-enteritis. Their feats are generally performed on a full stomach. On the other hand, in India powdered glass is not infrequently administered both to human beings and to cattle with intent to kill—in either case with some success. Glass bangles obtained from the bazaar and powdered have been administered in curry, and in some Oriental cities rat-catchers are said to employ this substance for destruction of vermin. In this country the employment of powdered glass is very rare, but recently it has been mentioned twice. In one case the food with which it was mixed was not eaten, and in the other case the employment was suggested, but there was no proof that it was ever used. The symptoms produced by powdered glass are in the main due to damage to the mucous membrane of the alimentary canal, and resemble those of gastro-enteritis. Pain may or may not be present. There is usually nausea and vomiting, and the vomit is often streaked with blood. Passage of the stool is painful and the fæces may contain blood. Perforation of a viscus has occurred. If the patient recovers—and the majority do recover—a chronic gastro-enteritis may ensue. The post-mortem appearances have shown considerable inflammation of the alimentary tract, with erosions, ulceration of the organs, and a considerable quantity of blood mixed with the contents. In cases where suspicion arises, great care must be taken to distinguish small particles of glass, and any organs reserved should not be placed in glass vessels. Analysis for powdered glass is simple; the organs are treated with hydrochloric acid and potassium chlorate, whereby the organic matter is destroyed and goes into solution, whilst any glass present is untouched. Filtration and examination with the naked eye or microscopically will then reveal the presence of particles to which confirmatory tests can be applied. With regard to the use of glass containers for food products, we recently pointed out their inferiority to metal containers in the matter of ready sterilisation; tins can more readily be made air-tight. Greater trouble in transport, loss from breakage, and the risk, whatever it may be, from ingestion of broken particles, may well turn the scale against the use of glass for food containers in this country.

PRE-OPERATIVE DIAGNOSIS OF EMBOLISM OF A RENAL ARTERY.

SOMETIMES logical reasoning and sometimes happy intuition which is little more than a guess, give a surgeon the clue to the correct diagnosis in a difficult case. The following case illustrates the felicity of a combination of clear reasoning powers with what can be best described as an inspiration. One morning Prof. P. Bull, who tells the tale,[1] found in his wards a woman, aged 35, who had been admitted on the previous day with the diagnosis of "acute abdomen." She was a domestic servant who gave no history of heart disease, rheumatic fever, or other illnesses, and who had been seized on the evening previous to her admission to hospital with violent pain in the upper abdomen. The following night was spent in pain and incessant vomiting. When examined next morning her medical attendant found rigidity and tenderness in the upper abdomen, and he very naturally suspected perforation of a gastric ulcer. In hospital the rectal temperature was found to be 38·1° C., the pulse 64, the respirations 28. A faint presystolic murmur was heard over the apex of the heart, and the second pulmonary sound was accentuated. The tenderness in the upper abdomen was greatest under the left costal arch. The catheter urine showed no pus cells, blood cells, or casts. The last menstruation had occurred five weeks earlier. These were the salient features presented to Prof. Bull when he first saw the patient, and when he proceeded to discuss with a class of students the differential diagnosis. As he ran over the various possibilities such as perforated gastric ulcer, intestinal obstruction, renal calculus, the suspicion suddenly occurred to him that the presystolic murmur and the sudden, acute abdominal pain might be relevant to each other. Wondering if the heart disease might not have given rise to embolism of the left kidney or renal artery, he catheterised both ureters and found that the left kidney had practically ceased to function. The injection of indigo-carmine told the same tale, and while the specific gravity of the few drops of urine drawn from the left kidney was only 1013, it was 1023 on the opposite side. With this and other evidence to support his diagnosis of embolism of the left renal artery, he performed nephrectomy and found the three main branches of the renal artery blocked by emboli, and the kidney itself mottled and the seat of numerous large infarcts. Death occurred suddenly 16 days after the operation, and again Prof. Bull scored a diagnostic success. He anticipated and found at the post-mortem examination that the mitral valve was obstructed by a large thrombus which had evidently become detached from the left auricle immediately before death. Thanks to the care with which the necropsy was performed, this thrombus was given no chance to slip back into the left auricle and thus puzzle all concerned as to the part, if any, it had played in causing the patient's sudden death.

DRUG IDIOSYNCRASY, WITH SPECIAL REFERENCE TO ADRENALIN.

THE term "idiosyncrasy" used in connexion with potent drugs denotes an imperfectly comprehended phenomenon. For example, a dose of chloroform which can be inhaled with safety by one individual will produce in another alarming or even fatal symptoms; the nature of these, ventricular fibrillation or vagal inhibition, may be demonstrated, but we have not the slightest knowledge which helps us to determine why the symptoms arise in one case and not in the other. The interesting communication from Dr. H. E. Symes-Thompson on p. 743, draws attention to idiosyncrasy in connexion with adrenalin and conveys a warning that may well be heeded. Adrenalin used in association with local anæsthetics is often not given credit for all the powers which it possesses. There has come down from the cocaine era a tendency to lay at the door of the local anæsthetic employed the blame for distressing symptoms which are actually due to the adrenalin injected and not to the anæsthetic. As long ago as 1910 Fröhlich and Loewi showed that intravenous injection of such a dose of cocaine into an anæsthetised cat as was by itself without effect produced a striking change in the pressor effect of a small dose of adrenalin. Before cocaine, 0·1 mgm. adrenalin produced a rise of pressure from 76 mm. to a maximum of 120 mm., having a duration of about two minutes; following 5 mgm. cocaine, the same dose produced a rise from 50 mm. to 140 mm., maintained during five minutes. Last year Sternberg showed that the same phenomenon followed the injection of novocaine and alypin, and he made it thereby clear that the action of cocaine was possessed by several local anæsthetics and was not dependent on some precise chemical structure. Another quite unlike substance having a similar effect is pituitary extract; when the rise of blood pressure produced by its injection in the pithed cat has passed off the effect of adrenalin is again much greater than before. More profitable comment may be made on the symptoms produced in the clinical cases recorded. It is natural to think that the effect of adrenalin is exerted peripherally and that the heart "consciousness," rise of blood pressure, sweating, and so forth, result from stimulation by the adrenalin of the sympathetic nerve-endings. It is unlikely that this is the case. In the cat an intravenous injection of adrenalin produces sweating on the pads of the feet, but not if the peripheral sympathetic nerve has been cut. Hence in this case the action of the adrenalin must be central rather than peripheral, and the stimulation it produces may follow as a consequence of central anæmia produced by the vaso-constriction. The possibility that idiosyncrasy to adrenalin is related to excessive thyroid activity also has experimental support, and as the evidence for an inter-relation becomes quantitative it becomes more acceptable. Holm and Bornstein have recently showed, for example, that the rise of blood-sugar produced by a dose of adrenalin in the rabbit is much less after thyroidectomy. All this points to the desirability of using adrenalin in very minute amounts, or, rather, in very dilute solution. Braun, whose authority in this matter is unimpeachable, regards a strength of 1 to 100,000 or 1 to 200,000 as the proper dilution for use with local anæsthetics. It is probable that in cases of dental extraction a dilution much less than this is often employed. The especial risk of adrenalin injection in association with light chloroform anæsthesia is now, of course, well recognised. When the two drugs are to be employed in the same case the injection must be made before the anæsthetic is begun or else after the patient is in deep narcosis. Whether suprarenin, a synthetic product, or adrenalin, the organic extract, is employed does not necessarily make any difference, for some of the suprarenins manufactured are equal in potency to natural adrenalin.

POST-SEROTHERAPEUTIC AMYOTROPHIC PARALYSIS.

THE list of sequels to the injection of a serum is already fairly long, and it has hitherto been customary to classify them in two main groups, according as they are early or late. Anaphylactic shock, for example, is an early sequel, whereas a rash, pain in the joints, albuminuria, œdema, myalgia, diarrhœa, and vomiting are a few of the many comparatively late sequels. Common to both groups is the fact that, provided the patient does not succumb at once, these reactions are only transitory, no permanent injury being inflicted. Unfortunately, the condition described as post-serotherapeutic amyotrophic paralysis is distinguished from the well-known sequels to serotherapy by its obstinacy, not to say permanency. Dr. J. Lhermitte records in detail[1] three cases observed during the war. The patients were soldiers given subcutaneous injections of antitetanic serum soon after being wounded and as a routine prophylactic measure. In no case could the dissociated amyotrophic paralysis of the brachial plexus which ensued be traced to the wounds for which the serum was given, nor to syphilis nor rheumatic disease of the vertebral column. The paralysis developed on the fourth, fifth, and eighth day respectively after the injection. The muscles involved were those of the shoulder and upper arm. The onset of the paralysis was associated with acute pain in the scapular and shoulder regions, but the pain passed off without leaving any tenderness on pressure over the branches of the brachial plexus or sensory disturbances. Apart from the amyotrophic condition, there was no trophic disturbance with the exception, in one case, of hypertrichosis of the posterior surface of the forearm. The paralysis did not pass off completely, and the amyotrophic condition seemed to be more or less permanent. After reviewing the recent literature on the subject, Dr. Lhermitte notes as significant that, with the exception of a single doubtful case in which antidiphtheritic serum was given, the cases hitherto recorded arose in connexion with the administration of antitetanic serum. This observation would suggest that antitetanic serum may, under certain conditions, have a toxic affinity for the nervous system whether the patients injected have, or have not, been sensitised by previous injections. The cases of amyotrophic paralysis observed in connexion with injections of antitetanic serum are obviously so rare that, interesting as this condition is, there is no need to regard it as an indication to withhold specific serum treatment in a case likely to have been infected by the tetanus bacillus.

THE PIRATES' WHO'S WHO.

IN this amusing book[2] Dr. Philip Gosse gives particulars of the lives and deaths of the well-known pirates and buccaneers whose names occur in history, romance, or both; in the latter case the achievements not always being borne out by Dr. Gosse's well-documented little biographies. Kidd, to whose terrific exploits the hidden treasure in the adventure story so often owes its accumulation, appears to have been not only a third-rate performer along incorrect lines, but largely a lawful and legal privateer, who was made the scapegoat of patrons like the first Earl of Bellamont (not Bellomont as in the book), the Duke of Shrewsbury, and other highly-placed persons with a keenly developed money sense.

Who is to be described with accuracy as a pirate is considered by Dr. Gosse in an informing preface, and the difficulty is apparent when we find Paul Jones included in the piratical book of reference, though with the statement that no one would to-day call him a pirate, and Sir Francis Drake excluded, though the author admits that he cannot exactly remove his earlier exploits from the designation of piracy. A piquant little biography is that of Captain Ben Johnson, the English midshipman, who deserted in the Red Sea, and proved so clever a sailor that he became admiral of the fleet of 14 vessels belonging to the Sultan of Ormuz. Johnson became a convert to Brahmanism, collected a crew of Englishmen round him of similar flexible religious tenets, held up English shipping, sacked towns, raided temples, and took vast plunder back to his oriental employer. But wearying of service he decided to strike out for himself, and ran away with the best vessel in the Ormuz fleet, a selected crew, and some £800,000, with which he reached Constantinople in safety. Indeed, he was received with acclamation, was made a Bashaw, and, says Dr. Gosse, "at the end of a long life of splendour died a natural death." Two of the longest biographies are those of Sir Henry Morgan and Captain Misson, both of which illustrate the broad range of the subject. Sir Henry Morgan was certainly a buccaneer, but he was also a privateering organiser with a legal status, which was afterwards recognised by his knighthood and appointment as deputy governor of Jamaica. Captain Misson was a religious and chaste pirate, who was for a time broken-hearted at the "death" of the captain of an English vessel from which he had taken £60,000; he married a native of the island of Johanna, a sister of the local queen, and founded a colony on socialistic lines of which he was elected Lord Conservator. He was a moral and religious person, and seems to have deserved better of fate than to be driven into the sea by the natives who rose against being conserved.

---

[1] Paris Médical, March 8th.

[2] London: Dulau and Co. 1924. Pp. 238. 10*s*.

There is a considerable literature of piracy to which Dr. Gosse calls full attention, but many of the volumes are rare and difficult to come by, consequently this alphabetical list will be found very useful. The author is to be congratulated on the original form in which he has given shape to his studies.

INFECTIOUS SCLEROMA IN CZECHO-SLOVAKIA.

IN a recent communication to the Committee of the International Office of Public Health, Dr. Joseph Cisler, professor of rhino-laryngology in the Czech University of Prague, stated that scleroma of the nose and throat was more frequent in Czecho-Slovakia than in Western Europe, and was steadily increasing in frequency. Of 75 cases of which he had received reports from various otological, laryngological, and dermatological clinics throughout the Republic, 53 had occurred in Bohemia, 14 in Moravia, 6 in Slovakia, and 2 in Subcarpathian Russia. The chief country of origin of scleroma is Poland, from which the disease has extended westwards to Silesia, Moravia, and Bohemia, southwards to Hungary, Croatia, Styria, and Carniola, eastwards to Russia, in the north-east to Lithuania, and in the north-west to Prussia. Poland, however, is not the only source of scleroma, as sporadic cases have been seen in all parts of the world, including Switzerland, Southern Italy, where it is endemic, Spain, Egypt, India, Japan, Oceania, and North and South America. The question of infection and contagion has not yet been satisfactorily settled, as the disease has not been experimentally inoculated into man or animals. Several cases, however, have occurred in the same family, and the fact that soldiers contracted the disease in Poland and Russia during the war is further evidence of its infectious nature. Of Dr. Cisler's 75 cases 36 were in men and 39 in women; the ages ranged from 16 to 69. Although formerly scleroma occurred only in the lowest classes of society, the rich are not exempt, as three cases in the present series were in well-to-do persons. The progress of the disease is very slow. The prognosis depends on the extension of the morbid process to the lower respiratory tract. Death was usually due to pneumonia, but in some cases which ran a rapid course the cause of death could not be discovered and was probably asphyxia. Treatment consists in systematic dilatation of the affected parts. Owing to the infective character of the disease vaccine treatment with Frisch's rhinoscleroma bacillus has been employed. Vymola has found that vaccination of this kind prevents the formation of fresh infiltrations. The more recent the lesions the more certain is the curative effect of vaccine treatment.

SARCOMA OF THE PENIS.

Dr. James J. Joelson,[1] of the Urological Clinic of the Peter Bent Brigham Hospital, Boston, who records an illustrative case, states that only 35 examples of sarcoma or endothelioma of the penis could be found on careful examination of the literature. One of these was described as a fibro-cellular tumour, 2 as fibro-sarcomata, 2 as spindle-cell, 4 as mixed-cell, 7 as round-cell sarcomata, 8 as melano-sarcomata, and 9 as endotheliomata, while 2 were not classified. The great majority occurred in men of the cancer age, but four were in younger adults, one in a boy of 8 years and two in infants. The commonest symptoms were pain in the penis or perineum, dysuria, and occasionally acute retention of urine. Most of the cases of endothelioma had priapism. Dr. Joelson has classified the cases into four groups according to their degree of malignancy. In the first group, which are the least malignant, the tumours do not metastasise freely, but tend towards formation of local recurrences which arise from the corpora cavernosa, less often from the sheath of the penis than from the erectile tissue. The second group, consisting of round-cell sarcomata, the great majority of which originate from the corpora cavernosa, are more malignant than the first group and show earlier and freer metastases. The third group, consisting of melano-sarcomata, though they metastasise freely, do not grow as rapidly as round-cell sarcomata. In all these cases the tumour arises at the distal end of the penis either in the glans or the prepuce. In the fourth or largest group, which consists of endotheliomata, the tumours are very rapid and malignant in their growth. Dr. Joelson's case, which occurred in a man aged 57, was an example of the second group, the tumour being a fibro-sarcoma of two years' duration, in which two local excisions and a biopsy had been performed. No evidence of metastases was apparent. Eight months after complete extirpation of the penis with dissection of both groins there was no evidence of recurrence or metastasis.

THE house and library of the Royal Society of Medicine, 1, Wimpole-street, London, W., will be closed from Thursday, April 17th, to Tuesday, April 22nd, both days inclusive.

WE regret to announce the death in London on April 6th of Dr. Alexander Haig in his seventy-first yeai. Some 40 years ago Dr. Haig's name became a household word in connexion with the part played by uric acid in the causation of disease.

AT the Council election next July of the Royal College of Surgeons of England there will be three vacancies, and the names of the eligible Fellows who are candidates follow in order of seniority: Mr. W. McAdam Eccles (formerly a member of the Council), Mr. W. E. Miles, Mr. H. J. Paterson, Mr. T. P. Legg, Mr. A. H. Burgess, Mr. Victor Bonney, Mr. Wilfred Trotter, Mr. Philip Turner, Sir Charles Gordon-Watson, Mr. Hugh Lett, and Mr. G. Grey Turner.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXVI.—THE TREATMENT OF HÆMORRHAGE FOLLOWING TOOTH EXTRACTION.

It is time that the procedure adopted for hæmorrhage in general surgery should be applied to a similar condition following the extraction of a tooth. The usual description of the condition given by the patient conveys the impression of great discomfort and anxiety. The bleeding had "lasted all night," and, in spite of keeping quiet by lying down and making applications of cold water or styptics of different kinds, large clots of blood formed in the mouth, and blood and saliva, the latter increased in quantity, continued to flow from the mouth, soaking many handkerchiefs (the number of times being given); sometimes there is given a volumetric measurement of the amount of blood presumably lost—e.g., "at least a pint."

The Disadvantages of "Plugging the Socket."

The doctor is sent for, and, finding further local applications such as adrenalin and ice useless, feels compelled to adopt the classical method of treatment by "plugging the socket," a procedure he delays for as long as possible on account of the great pain and discomfort caused. At first it not infrequently fails, and the operator, thinking perhaps it is due to tender-heartedness on his part, or to the want of courage on that of the patient, makes a more heroic attempt. In due course the hæmorrhage is arrested, usually with considerable injury to the parts involved; more often than not a varying degree of necrosis results, the soft tissues become swollen, and there is practically always some sloughing. Such a picture may be regarded as an exaggeration, but from a considerable experience I venture to state that it is not uncommon, and my object in setting it out is to raise a protest against the method of plugging the socket in general use.

Precautions in Extraction.

In considering the question of treatment, it is necessary to determine what are the causes of the hæmorrhage, how it can be prevented, and if it occurs, how it can most easily be arrested. It practically never occurs if a tooth be extracted without laceration to the soft parts or fracture of the alveolus—the first principle, therefore, is to extract the tooth with as little damage to the tissues as is possible. An error, I believe, has been committed in teaching dental and medical students, by emphasising an outward movement during extraction, which frequently leads to fracture of the outer alveolar plate. It would be more correct to urge a loosening of the tooth, and then its withdrawal in its long axis. If, however, the character of the tooth is such that this method is impossible, and the alveolus is broken, the question of possible hæmorrhage should immediately arise in the mind of the extractor. Should it occur, the general surgical principle laid down of determining where the bleeding-point is situated applies equally in the case of a tooth socket. The hæmorrhage will be found in practically every case to be situated in the muco-periosteum, which has been torn from the bone (the margin of the socket usually having been fractured), and never from the socket itself. In those rare cases where the hæmorrhage comes from the bone, a large part of the socket has been removed in the effort to extract the tooth. Even in cases where so severe an operation has been necessary, it is improbable that a vessel of an appreciable size has been damaged. In the operation of removing some inches of bone from the iliac crest for bone grafts, hæmorrhage is at times persistent, but is overcome without difficulty by placing a blunt-ended instrument over the bleeding-point, and giving a gentle tap with a hammer. Such hæmorrhage, however, implies an operation scarcely within the category of ordinary tooth extraction.

An Alternative Technique for Stopping the Hæmorrhage.

The procedure for treatment in cases of hæmorrhage should be as simple as possible, and great care should be taken to avoid injury of the parts. The muco-periosteum should be turned back gently and any loose fragments of bone removed. Any difficulty in determining from where the blood is coming may be overcome by applying lateral pressure to the soft tissues of the socket, first to one side and then the other, sterile gauze being used for the purpose. Where a fragment of alveolus has been removed, and pressure is applied in this manner, the hæmorrhage in most cases is completely arrested. Should it recur on removal of the pressure, a roll of gauze upon which the patient can close the jaws is often effective, but the pad must be carefully applied so that pressure is brought to bear directly, or by tension on the gum, upon the bleeding vessel. Direct pressure applies particularly to hæmorrhage from the quite large vessels situated in the muco-periosteum around a third mandibular molar, a tissue which is apt to be torn from the bone during the removal of this tooth. With other teeth the bleeding-point is usually away from the upper part of the socket, when the muco-periosteum must be carried over the bone when applying the gauze. Should this procedure fail, one stitch through the gum, pulling the soft tissues together across the socket, will usually succeed, but if there is any doubt, greater security may be assured by a stitch commencing on the side which is not bleeding, then taken through the bleeding side, and back again through the same side, and then back through the original flap. The vessel may be included in the loop, but when this is impossible the tension will usually suffice.

Ligature of the bleeding vessel may be undertaken, but is difficult to carry out, as one is apt to increase the tearing of the flap. If the hæmorrhage is upon a free surface, there is little difficulty in arresting it, but when it is situated more deeply, there is considerable difficulty in applying artery forceps. If, however, the vessel needs the direct application of a ligature, this is best carried out by including it in the loop of the ligature, introduced with a curved needle.

Should the simpler methods fail, it is undoubtedly advisable to make a local injection of novocaine with or without adrenalin, in order to render it easy to carry out the treatment, and to avoid injury of the parts as much as is possible. If adrenalin is used, it is necessary to remember that when the action of the drug passes off the hæmorrhage may recommence.

In cases in which the clotting of the blood is imperfect, judging from the records available, hæmorrhage would appear to be of greater frequency after tooth extraction, than from injury to other parts of the body. How often do they occur during general surgical procedure? I would venture to state that they will be found to be of far less frequency than is generally implied if the hæmorrhage is dealt with in a surgical manner.

Summary.

The treatment may be summarised as follows:—

1. The removal of fragments of fractured alveolus.
2. Lateral compression of the muco-periosteum, which can be continued by the patient.
3. Compression between the jaws of a pad applied over, or making tension upon the vessel.
4. Tension derived from stitching the flaps of muco-periosteum over the socket.
5. Ligature or stitch at actual point of hæmorrhage.

I would add that the most important point of all is that during extraction of a tooth no laceration of soft parts or fracture of alveolus should occur if it can possibly be avoided.

SMALL-POX AND VACCINATION:
DR. KILLICK MILLARD'S VIEWS.

BY JOHN C. MCVAIL, M.D. ST. AND., LL.D., F.R.F.P.S.

IN his writings on the subject of small-pox and vaccination Dr. Killick Millard has related how in his early days he lectured and conducted a newspaper controversy in support of vaccination on ordinary lines. That was before he became medical officer of health for Leicester. In 1902, a year or two after he had gone to that town, he gave an address to a branch of the Society of Medical Officers of Health on "The Rôle of the Anti." It was an interesting deliverance, exhibiting sympathy with people of eccentric views on various subjects, and saying much generally in favour of the "anti-" minded. In doing so he made, as it seems to me, one serious mistake. "First and foremost," he said, "the most striking feature of the 'anti' is his *independence*." The "anti" cares nothing for authority nor authorities. "So far from his being prejudiced in favour of the views of the majority, his sympathies are usually with the minority, and if the minority is a small one, so much the better." But—and it should have been obvious to Dr. Millard—prejudice against the majority is not independence. Independence connotes impartiality of attitude and of judgment. The "anti," instead, does not weigh opposing views neutrally and according to their merits. He is repelled by considerations which attract the ordinary intellect, is attracted by whatever appeals to the smallest number of minds, is led to defy the laws of evidence, to reject natural conclusions, to evade facts, and to resort to sophistries in substitute for reasoning. No man indeed is more prejudiced than the "anti." But Dr. Millard has always had a strong and laudable love of independence, and his fundamental error that the "anti" is independent has sadly distorted his vision. It is a great pity, for if I may say so without assumption of authority, Dr. Millard is a man of marked ability, energy, and assiduity.

I have read with much interest in THE LANCET of Feb. 9th his criticism of my address to Members of Parliament. His opinion of it differs totally from that expressed in a leading article in THE LANCET of Oct. 13th, 1923, and I might have left the two views to be measured against each other, but that would have been relying on abhorrent "authority," and so, without following Dr. Millard into every detail of his review, I proceed, if the Editor will allow me, to comment on some of its salient features.

1. *Infant Vaccination.*—Dr. Millard charges me with vagueness in the use of the term vaccination, and with, in that way, unintentionally misleading, or tending to mislead, my audience. He says, referring to my remarks on the Poplar outbreak of small-pox last year, "many of his hearers would probably think that by 'vaccination' he meant infant vaccination." Again, with reference to the proposition that small-pox can be prevented by vaccination, he asks, "What exactly does he mean by it, or rather, what would his hearers be likely to think he meant by it?" and "if he meant, or if his hearers thought that he meant (as most of them no doubt would think), that small-pox can be prevented—i.e., effectually controlled—*in the community* by a State system of infant vaccination, then I submit the proposition cannot be substantiated."

This supposition that I was suggesting either by silence or by speech, either intentionally or unintentionally, that primary vaccination is enough, or, in other words, that revaccination is not necessary for protection of the community, fairly astonishes me. He quotes me correctly as saying, "In whatever way the data are questioned, from whatever angle the problem is viewed, the conclusion is the same." But he seems entirely blind to the fact that two or three lines later I go on to say—and here I may be allowed to italicise the crucial words—"if the diminution in small-pox be considered in places and times, side by side with the practice of *vaccination and revaccination*, strong proof of causal relationship appears." In the next paragraph I speak of "countries which are *well vaccinated and revaccinated*," and after that of "classes which are *well vaccinated and revaccinated*." In some places the page is bespattered with references to the value of and need for revaccination. I point out how at the time of the Royal Commission the medical press held that "vaccination and revaccination were alike necessary for control of small-pox." In one passage, indeed, I speak not merely of revaccination, but of renewed revaccination in presence of small-pox. But independently of the fact that my address was full of revaccination, it is surely out of the question to suggest that Members of Parliament are not aware through their general knowledge that, as expounded times without number not only in THE LANCET and other medical periodicals, but also in the lay press and otherwise, the medical profession regard revaccination as essential for communal protection. In fact, I can call to mind only one member of the profession who has ever in the present generation confined the broad term vaccination to the period of infancy. That member is Dr. Killick Millard. In bringing himself more or less into line with the Leicester anti-vaccinationists who boast about that town's alleged "abandonment of vaccination," he made the remarkable reservation that when he said "vaccination had been abandoned," all he meant was "infantile vaccination as established by law in this country," or again, "universal vaccination." He thus himself deliberately gave to the term the limited meaning which he now, without the slightest justification, charges to my account. And by this device, though with a somewhat falsetto voice, Dr. Millard enabled himself to join in the chorus or duet that "Leicester had abandoned vaccination."

2. *The Story of Kilmarnock.*—I have incurred Dr. Millard's reproof by telling the Members of Parliament the story of small-pox in Kilmarnock in the eighteenth century. To me it seemed quite reasonable, and perhaps interesting, to give from an authentic source an illustration of what small-pox was in respect of prevalence, fatality, and age-incidence in this country in pre-vaccination times, and to go on to tell the audience that "it was in the midst of these conditions that Jenner came with vaccination, and though he made mistakes, it is no exaggeration to say that in such circumstances his conception that cow-pox was small-pox of the cow and would prevent small-pox in man was the direct means of saving more lives and averting more misery than it had ever fallen to the lot of a human being to accomplish from the dawn of history up to Jenner's day." He charges me with an attempt to create prejudice —"(of course this is not intended in an offensive sense)"—and with acting the part of a clever barrister. But surely I may beg my censor to note what he himself calls attention to in the same page. At the beginning of my proposition that "small-pox can be prevented by vaccination," I wrote "the mortality from small-pox is much less since vaccination was introduced. That in itself proves nothing." Dr. Millard says that I "admit" this. Then why does he not give me credit for the admission in mitigation of my "harrowing picture" of old Kilmarnock? It appears in the same address to the same audience, with only a page between. Did he want me to break the reasoned sequence of my address and jump from the middle of the first proposition into the second, lest during the intervening minutes some Member of Parliament might feel unduly stirred? Does he think Members of Parliament are mental defectives?

3. *The Vaccination Acts.*—Dr. Millard complains not only of what I have said, but of what I have not

said. In his opinion, when I was addressing Members of Parliament, "the question, and really the only question which concerns them, is the necessity or otherwise of *compulsory infant vaccination*." Here I differ from him absolutely. Compulsion or non-compulsion is a question not for doctors as doctors, but for the legislature. That is a view urged by me as long as a quarter of a century ago. The duty of the medical profession is to inform Parliament and the public of the truth about vaccination, its value and its safety, and having done so, to leave Parliament to deal with the law. Indeed, having begun my address by telling the audience about both mild small-pox and severe small-pox, I ended it with the following exordium: "If Parliament disbelieves in vaccination it should repeal the Acts. If it believes in vaccination it should exercise some degree of pressure in support of its belief, not by attempts at compulsion which would do far more harm than good, but by drawing some practical distinction between a parent no doubt wrong-headed yet sincere in his conviction that vaccination is evil, and another parent who is merely indifferent or neglectful."

Dr. Millard, however, would presumably take a very different course. He would plunge right away into politics, and would urge that all legislative pressure towards infant vaccination should cease. He would explain that this is not because he doubts its anti-variolous power, but, paradoxically, because he is well aware of it, and wishes that children or adults attacked by the classical type of small-pox should, owing to want of vaccination, have the disease in a form so severe as to make it all the more certainly and quickly diagnosed and isolated. That would be done in the interests of others who, or whose parents, had refused or neglected to take advantage of the protection which Dr. Millard knows vaccination to confer. Severe small-pox, of course, has a high fatality-rate, and leaves much disfigurement and some blindness amongst survivors. That would be part of the price paid vicariously under Dr. Millard's scheme by those who would remain unvaccinated as a result of abolition of all that remains of obligation under the Act of 1907.

He thinks that in this way much more would be gained than lost, otherwise he would not have advanced the proposition which I have stated in what appear to me to be its real terms, though they would not be his. But, however expressed, surely the scheme is utterly and ethically wrong. As medical men we have no right to gamble with human life and health in any such fashion. No doctor should dare to endanger the life of his child patient, John Smith, by refraining from protecting him against small-pox, in the hope that thereby John Brown and John Jones may ultimately, in the manner above indicated, escape small-pox. No doctor refrains from doing his best to cure or prolong the life of a tuberculous patient because he might subsequently infect others. It is our elementary duty to save a life, whether by protective or curative treatment whenever and wherever we have the opportunity, and to leave the final outcome in other hands. At the best we are poor purblind blundering creatures, but our ability remains the measure of our responsibility. I am not, however, going to argue about ethics, but our case is not confined to a question of moral principle. With very rare exceptions the medical profession holds that, to protect from the risk which alarms Dr. Millard, the unvaccinated should resort to vaccination, and the once vaccinated to revaccination, instead of trusting themselves to an extraordinary scheme, whereby those who are at present protected by infant vaccination should be replaced by a fresh community of unvaccinated with the view that, if attacked by small-pox, they should probably have a severe and unmistakable even if occasionally a fatal attack. Is not, let me ask, Dr. Millard's attitude as between the safety of these two sets of children: those whose parents bring them for vaccination under the present law, and those whose parents negligently or obstinately decline so to do—an indication of the "anti" development of mind?

4. *Individual and Communal Protection.*—Referring to my having pointed out that vaccination in this country has never been really but only technically compulsory, Dr. Millard remarks, "surely this is a verbal quibble." It is instead an incontrovertible and pertinent fact, and it was so when I pointed it out so long ago as 1898. Very oddly, the evidence which he adduces that this is a quibble demonstrates just the opposite. He shows how the Leicester Guardians failed even by prosecution and distress warrants to secure vaccination. But that is exactly my contention. Vaccination never has been compulsory. Dr. Millard evidently attaches much importance to a distinction between protection of the individual and protection of the community. Here he is under the influence of a false analogy between the old practice of small-pox inoculation and the modern practice of vaccination. Variola, whether inoculated or caught in the natural way, was infectious; vaccinia is not. But what after all is the difference between individual and communal protection? A community is made up of individuals. If one person is duly vaccinated he is safe until he needs revaccination, and after it he is safe again. If ten are so protected they are safe; if ten thousand, they are safe, and so on to infinity. But there is one advantage in communal as distinguished from individual vaccinal protection. Its value increases by a kind of compound interest. Even if in the protected community there is some small drift towards renewed susceptibility owing to lapse of time, the one is guarded by the many—he has around him a cordon of vaccination. This leads to the question of vaccination in Germany.

5. *Germany.*—Referring, before the war, to the remarkable immunity of Germany from small-pox Dr. Millard repeatedly bore testimony to the value of its system of primary and revaccination. He wrote in 1911[1]: "I quite believe that if the German system (including a third vaccination of all males) could be adopted in this country equal results would be obtained," and in the same connexion he said in 1914 that "a system of universal vaccination and revaccination and re-revaccination, where it can be effectually enforced, will practically abolish small-pox."[2] But in 1917, when news began to arrive about small-pox outbreaks in Germany, his attitude underwent a remarkable change, or at least it was very differently revealed.[3] "Behold," he cried, "Germany, the much vaccinated and revaccinated Germany, which for years past has been held up as a shining example and pattern to the world in the matter of vaccination, is now suffering from several serious outbreaks of small-pox in various parts of the country! Surely it is time that existing theories about vaccination were re-examined." Now, in The Lancet, he writes in similar fashion. But it was he who so shortly before the war had declared his belief that the German system effectually enforced would "practically abolish small-pox." When I come to the relationship of the mild type of small-pox to the case of Leicester it will appear that this *volte face* about Germany does not stand alone.

But in his outburst over the occurrence of small-pox in Germany all sense of proportion deserts Dr. Millard. When Germany's testing time came in the great war, when hundreds of thousands of prisoners from ill-vaccinated Russia were brought within its borders, Germany experienced in its 60 million population nearly 11,000 cases of small-pox. Let us take 11,000 without any limitation of "nearly." There was thus one case of small-pox in six years to every 5500 of the population. When Leicester's very mild test came in 1902–04, not in war, but in peace, there were 715 notified cases. Writing of the 1903 epidemic he remarked, regarding unrecognised small-pox (*Public Health*, Vol. xvi., p. 618), "I believe there were many other cases which never came to light at all," but, confining the comparison to those notified, and taking the Leicester population at 220,000, there was in 20 months one case of small-pox to every 300 of population, as against, in Germany in six years, one case in every 5500 of population. Yet, according to Dr. Millard, the broad results of the Leicester experiment have been "successful beyond all expectation," whilst Germany "has fallen so sadly from grace." And if Dr. Millard holds that account must be taken of the years in which Leicester (like the rest of England) has had little small-pox, let him also take account of the wonderful freedom which Germany has enjoyed since it adopted systematic vaccination and revaccination, notwithstanding the ill-protected condition of neighbouring nations.

---

[2] The Vaccination Question, p. 191.
[3] Brit. Med. Jour., 1917, i., 409.

6. *Temporary Protection.*—Dr. Millard insists again and again that vaccination gives only temporary immunity from small-pox. The way in which he stresses the word "temporary" is notable. He says that "of course" the altered age-incidence of small-pox is a perfectly sound argument for proving that vaccination confers temporary immunity against small-pox in the individual, but "it may simply shift the incidence of small-pox from one age to another." The Royal Commission concluded that the duration of highest protection might fairly be said to cover a period of nine or ten years, that then its efficacy "against attack rapidly diminishes, but that it is still considerable in the next quinquennium, and possibly never altogether ceases," that its efficacy to modify the disease diminishes more slowly, and during the later period of life it is "still very considerable." With a slight reservation as to duration of the highest protective potency, Dr. Millard has professed his entire acceptance of all this, yet he says infant vaccination "may simply shift the incidence of small-pox from one age to another."

About the Poplar outbreak Sir William Hamer stated, as noted in my address, that the three shortest intervals between primary vaccination and attack were 14, 16, and 16 years respectively; that the three shortest intervals between primary vaccination and a *fatal* attack were 43, 44, and 49 years respectively; and that the ages of the other fatal cases vaccinated in infancy were 58, 66, 66, 67, 69, 72, and 73 respectively. But, after all, to adopt Dr. Millard's view, the man of 73 had only had "'temporary" freedom from the disease. He might otherwise have lived to be 100.

In my address I said that "In towns where small-pox prevails more of the unvaccinated than of the vaccinated are attacked especially if the vaccination is recent." In illustration of that statement I gave the following figures, taken from a table in the Royal Commission report, of attack-rates among the vaccinated and unvaccinated in invaded houses. With reference to what is, or was, a frequent allegation of opponents of vaccination, that higher attack-rates and death-rates among the unvaccinated were to be accounted for by their constituting a weakly class whose vaccination had been postponed or omitted owing to the state of their health, I pointed out that this could not be said of centres of anti-vaccination where the operation was, in fact, entirely optional, these places including Leicester, Gloucester, and Dewsbury. On the contrary, if, as has been argued, vaccinated children have their blood poisoned by vaccination, they would more readily succumb to infection than the unvaccinated, whereas the opposite is the case.

—	Incidence-rate under 10 years of age.		Incidence-rate over 10 years of age.	
	Vaccinated.	Unvaccinated.	Vaccinated.	Unvaccinated.
	Per cent.	Per cent.	Per cent.	Per cent.
Warrington ..	4·4	54·5	29·9	57·6
Dewsbury ..	10·2	50·8	27·7	53·4
Leicester ..	2·5	35·3	22·2	47·6
Gloucester ..	8·8	46·3	32·2	50·0

But Dr. Millard's sole reply is, "This, I submit again, only proves that vaccination confers temporary immunity on the *individual*," and that "small-pox inoculation would show the same effect." That is positively all that these facts convey to his independent mind.

Perhaps his most singular remark in this connexion is with regard to the immunity of nurses. He says: "I quite accept the immunity of small-pox nurses as definite and convincing evidence that by vaccination (repeated as often as necessary) it is quite possible temporarily to protect *individuals* against small-pox, but I submit emphatically that this is no evidence that infant vaccination will, or does in fact, protect the community." He squanders emphasis here in denying what no human being in his senses ever dreams of asserting. How could the protection of adult nurses prove that infant vaccination would protect the community? If infant vaccination had that power there would be no need for revaccination of nurses, they being part of the community. But vaccination "repeated as often as necessary" gives *permanent* not *temporary* protection. If a man travels far enough east he ultimately reaches the west, and Dr. Millard's anxiety to use the word temporary wherever he can find room for it lands him in the strange position that temporary and permanent are exchangeable terms, meaning exactly the same thing.

7. *Absent Small-pox.*—He says I might have pointed out that "in spite of the steadily increasing neglect of infant vaccination throughout the country, small-pox has become, during the past two decades, one of the rarest of the zymotic diseases, and the mortality caused by it has been negligible." But here he is putting the cart before the horse, and is adopting one of the most obvious sophistries of the present day anti-vaccinationist. When vaccination is practically voluntary, the main stimulus to its performance is the presence of small-pox. In Britain we have been extraordinarily well off in respect of small-pox, both as to low prevalence and low fatality for two decades. On that account there has been very little vaccination. And so, it will always be possible to exhibit, as lately in an extensively circulated table, in two parallel columns, much vaccination and much small-pox, little vaccination and little small-pox. But it is the latter fact that accounts for the former. The table, for example, shows that in 1872, when 85 per cent. of the births were vaccinated, there were fully 19,000 deaths from small-pox, whilst in 1921, when only 38 per cent. of the births were vaccinated, there were only five deaths from small-pox. And it may safely be said that if in 1924 there were 10,000 deaths from small-pox the vaccinations, including revaccinations, would be in millions. In Glasgow the anti-vaccinationist could show from p. 8 of my printed address that there were in 1901–02 over 400,000 recent vaccinations, and yet nearly 1800 cases of small-pox occurred. But when small-pox diminished, vaccination diminished also. In so far as vaccination is carried on when small-pox prevalence is at a low ebb, it is an insurance against future risk, so that the rare accident of a death in any way related to vaccination is not to be measured, as Dr. Millard would wish, against current deaths from small-pox, but against what is to be encountered when variola reappears.

8. *Tetanus and Vaccination.*—Dr. Millard says I might have mentioned to my hearers "a series of disasters which occurred in the State of New York a few years ago, as a result of which it was decided by the State Legislature virtually to repeal the enactment which made universal vaccination compulsory." This question was raised by Dr. Millard in 1922, when he wrote: "I can say, however, that in 1915 the State of New York, acting on the advice of their health officer, Dr. Herman Biggs, virtually abolished compulsory vaccination by repealing the regulation under which all children had to produce evidence of vaccination before being admitted to school. Dr. Herman Biggs, who is one of the most experienced and distinguished members of the Public Health Service in the States, gave this advice, I understand, because he

had come to believe that the disadvantages, in the way of injury to health caused by child vaccination, more than outweighed the advantages to be gained by immunisation against a rare disease like small-pox." It chanced that Prof. Mazyck P. Ravenel, M.D., of the University of Missouri, read this statement, and sent to Dr. Herman Biggs a quotation from Dr. Millard's letter. He received from Dr. Biggs a reply, which began: "The quotation as regards my attitude towards vaccination is, of course, incorrect." He went on to tell how in a great vaccination campaign in the State of New York in 1915 there had been a number of cases of tetanus, with 11 deaths, that in consequence legislation was introduced which would have repealed all the provisions of the vaccination law and would have injured the whole public health programme, that to insist on compulsion under the existing conditions was not justifiable, and that he had therefore consented to amendment of the law. This was a very different attitude from that attributed to him by Dr. Millard—"that he had come to believe that the disadvantages in the way of injury to health caused by child vaccination more than outweighed the advantages to be gained by immunisation against a rare disease like small-pox." Indeed, there is not a syllable by Dr. Biggs which excuses these words. Dr. Millard replied, expressing regret, "if" he had misrepresented Dr. Biggs, but at the same time expressing pleasure in having guarded himself by the reservation "as I understand." He went on to explain that he had been told about the matter by an officer of standing in the New York State Service, and had made a written note at the time of what he was told.

Eleven deaths from tetanus introduced by vaccination would most certainly and most justly be regarded in this country as a great disaster. But no event of the sort has ever been recorded in England. Dr. T. D. Acland, who investigated the whole subject of vaccinal injuries for the Royal Commission, was acquainted with only one case in more than five million consecutive vaccinations in this country, and even in it there was no evidence that the tetanus was invaccinated. In the Registrar-General's office the books, in which are set down all references to vaccination in certificates of death, go back for 29 years—from 1895 inclusive—and while diseases like measles, whooping-cough, bronchitis, erysipelas, &c., are mentioned, tetanus finds no place whatever in the volumes. Besides, I was addressing members not of the American legislature, but of the British House of Commons. Yet Dr. Millard in his anxiety that nothing should be missed which could possibly be alleged against vaccination, would have had me look across the Atlantic in search for such material. Hearsay was quite enough to satisfy him that Dr. Herman Biggs agreed that the disadvantages of vaccination outweighed its advantages. Similarly he chanced to read in a lay newspaper that all of 22 who died of small-pox in the Poplar outbreak had been vaccinated in infancy, and he wrote to the medical press that "it is interesting to learn" this, with the result that when it was pointed out to him by someone that he was wrong, he had again to express his regret, but again with a reservation—this time that the statement so "interesting to learn" was "quite immaterial" to his main argument. The readiness with which he accepts and gives currency to such a story is typically "anti."

9. *Leicester.*—Naturally Leicester bulks largely in Dr. Millard's thoughts, and he may be excused for complaining that I did not say more about it in my address. Well, it would have been quite easy to occupy the whole available time with the case of Leicester, and it would have made quite a good text, but the title of the address was Small-pox and Vaccination, and the discourse had to be of a wider scope. I had no occasion to evade the issue, however, and as Dr. Millard feels aggrieved I shall indicate what might have been said had the subject been Leicester.

(*a*) *Unfulfilled Prophecy.*—Dr. Millard regards few of his compositions on the subject of vaccination and small-pox complete unless they contain reference to one particular passage in "Vaccination Vindicated," published by me 37 years ago. I have noted it in *Public Health* in 1904, in his book "The Vaccination Question" in 1914, in *Public Health* in 1917, and now once more in his article in THE LANCET. I do not recollect paying attention to it until the Milroy lectures in 1919, but then I took the trouble to call his attention definitely to the mangling to which he had subjected the passage in question. I wrote as follows in 1887: "In Leicester when its time arrives we shall not fail to see a repetition of last century experiences, and certainly there will afterwards be fewer children left to die of diarrhœa. It is to be hoped that when the catastrophe does come the Government will see that its teachings are duly studied and recorded." And also: "Throughout the country there has been nothing approaching an epidemic since 1870–73, and Leicester has had little chance of getting its 'immunity' tested. When another great outbreak occurs among the susceptible population of England it will be time enough then to see how Leicester comports itself under the ordeal." In Stevenson and Murphy's "Hygiene" in 1893 I repeated the reservation that "since the Leicester experiment was begun it has not been subject to the test of any general epidemic like that of 1870–73." That obviously was in my view the criterion of Leicester's protection—the occurrence throughout the country of an epidemic approaching that of 1870–73. The matter is of little moment, but as Dr. Millard evidently regarded it as of great polemic value I specifically pointed out to him in the Milroy lectures that he "does not give the full quotation, and in 'The Vaccination Question' he definitely excises my reference to the 1870–73 epidemic."

Now, in THE LANCET in 1924 he makes the same excision, which perhaps may be taken as an incidental indication of his attitude to the whole subject. The question is not what he thinks of the point I raise, but what I think, and he has no right whatever to exclude from the quotation the words I have asked him to include.*

Apart from the personal question, two important considerations have to be borne in mind, first, that glycerinated calf lymph is now available to meet the needs of any epidemic anywhere, as compared with the meagre quantities of humanised lymph which alone were readily obtainable from the weekly vaccinations of babies at the time I wrote; secondly, the substitution throughout the provinces of the mild American type of small-pox for the virulent Eastern type—a substitution which no one foresaw in the days when the pandemic of the seventies ruled the conceptions of the profession and the public as to what small-pox meant in epidemicity, infectivity, and mortality. And so little am I troubled by the fact of having been no more able than anyone else to visualise the coming change, that, after all, here and now I give Dr. Millard full permission—though he no more needs it than a man needs the gift of the freedom of his own city—to go on mangling that quotation throughout the rest of his life.

Curiously, in 1917 and 1919 Dr. Millard himself has had some hankerings after prophecy. Referring to what appeared in the Milroy lectures about the possibility of the disappearance of small-pox, and, consequently, of the need for vaccination, he said: "I go a little further, and say that as small-pox has *already* virtually disappeared so also has the need for infant vaccination. In this matter I am merely a few years ahead of Dr. McVail, that is all." But he was at least a few years too far ahead of me. Since 1917, when there were only seven cases, the subsequent years have successively had 63, 311, 280, 336, 973, and about 2500 cases, whilst in the first eight weeks of 1924 there have been 563 cases. If this goes on someone may by and by accuse him of unfulfilled prophecy, but if so I hope he will be quoted correctly.

---

* Too late for notice in the text I find that in "The Medical Officer" of March 15th Mr. Millard once more makes the quotation and once more excises the words in question.

(*b*) *The Method*.—Had I gone briefly into the discussion of Leicester and its method I would have had to state that the story of Leicester being well vaccinated before the pandemic of 1870–73 was apocryphal (Dr. Millard being partly responsible for the Apocrypha); that the Leicester method was largely a paper method which sufficed for anti-vaccination propaganda when small-pox was absent, but broke down in point after point when small-pox was present; that, indeed, what was abandoned when small-pox came was not vaccination, but the method itself in its most advertised features; that vaccination was at once resorted to, that hundreds of contacts were vaccinated, and that in order to make more room for small-pox the hospitals were emptied of scarlet fever, which had to be allowed to run its course in the houses of the patients.

It would have been a pleasure to add (and I wrote to that effect in 1913) that by heroic measures like these, which were thoroughly justified in the dangerous condition of the population in respect of liability to small-pox, Dr. Joseph Priestley succeeded in limiting the epidemic of 1892–93 to 355 notified cases in 15 months, and that Dr. Killick Millard by similar unwearying devotion to duty was able to limit the disease in about 20 months in 1902–04 to 715 notified cases. One factor which contributed greatly to the limitation of cases alike in 1892–93 and 1902–04 was the general mildness of the type of disease, and its consequent low infectivity, notwithstanding the greater likelihood of cases being missed. But unfortunately the credit thoroughly well earned by Dr. Millard for his limitation of the prevalence of the disease is somewhat tarnished by a subsequent want of candour. In 1904 he freely acknowledged how much he owed to the attenuated strain of the virus. "I fully realise," he said, "that the results of the experiment in the future may be very different from those achieved in the past. Moreover, it may have been merely a lucky coincidence that the two epidemics which have occurred since vaccination has been abandoned have been of such an exceptionally mild type. The epidemic at Gloucester was far more fatal."

He was here very prudently and properly reserving his opinion as to what might happen to the town if it were invaded by the old 1870–73 type of epidemic variola. Fortunately no such calamity has befallen the Midlands of England, and Leicester has shared in the unparalleled freedom from severe small-pox. But in 1914, ten years later, he concluded he could safely destroy the bridge he had built for possible retreat. And in doing so he rather comically wrote as if it was not he who had constructed it for himself, and he proceeded to jeer at those to whom he would like to attribute it. "Many people," he writes, "appear to think that, owing to some extraordinary good luck, small-pox has never come to Leicester in a fatal or epidemic form since vaccination was abandoned." Again, "Hitherto it had often been alleged that the 'Leicester method' had never been adequately tested, and that Leicester had been lucky." Thus, under the curious pseudonym of "Many people" he attacks himself for having been so needlessly wise in 1904, and he deserts the sound view of the debt Leicester owed to the mildness of type of its small-pox for the thesis that "it seems more reasonable to ascribe the low case-mortality to the comparatively good sanitary state of the town." I shall now show how Dr. Millard supports that hypothesis.

(*c*) *Mild Small-pox.* — Dr. Millard [4] gives the following table.

Small-pox Epidemics in Leicester.

Year.	Population.	No. of cases.	No. of deaths.	Attack-rate.	Mortality.	Case-mortality
1871–72	100,000	(3300)*	358	(33·0)*	3·58	(10·8)*
1892–93	183,000	355	21	1·94	·11	6·0
1902–03	220,000	394	21	1·79	·09	5·3
1903–04	224,000	321	4	1·43	·02	1·3

* Estimated only.

Concerning the lessened severity shown in the table, he remarks that, "Obviously, some factor other than vaccination has been at work, and it is reasonable to suggest that improved sanitation is the most probable cause." The figures for 1871–72 are only an estimate, but the pandemic of which they were a small item was of extraordinary extent and this country has never again had such a visitation. Let it be noted, however, that the greatest proportionate diminution was between the third and fourth epidemics, the latter having barely one-quarter of the fatality-rate of the former. The third epidemic was that of 1902–03, the fourth that of 1903–04. But the first known case of the 1903–04 outbreak began less than six weeks after the onset of the last of the cases of 1902–03; in fact, the hospital had to be reopened within less than one week of its closure. Yet Dr. Millard thinks it "reasonable to suggest" that the reduction of fatality from 5·3 to 1·5 per cent. was most probably due to sanitation. Sanitation having taken 20 years to reduce the rate from 6 to 5·3, suddenly, in a period of weeks or months, reduced it to 1·3. And Dr. Millard does not seem to be joking in submitting his table. The fact is, as already urged, and as realised by Dr. Millard at the time, Leicester was sharing in the attenuated strain of small-pox which prevailed in the provinces of England in 1902–05. Though the Leicester fatality rate in the epidemic prevalence of that time was very low it was by no means the lowest. Everywhere else, so far as I know, the very favourable case mortality was thankfully accepted as due to the mild strain of small-pox. But that view is no longer good enough for Leicester, and so Dr. Millard submits the alternative on which I have commented.

The cause or causes of the remarkably diminished prevalence and fatality of small-pox since the beginning of the present century is a subject of the greatest epidemiological interest, but it cannot be entered on here. Epidemic diseases change from age to age and from generation to generation. Up till 1917 small-pox was retreating whilst influenza has advanced. The out-and-out opponent of vaccination would attribute the decline of small-pox to sanitation without attempting to analyse that term, whilst he is beginning to revive the old fable that increase of cancer is due to vaccination.

Concerning the future, I may recall that more than 30 years ago, probably before Dr. Millard had begun controversy in support of vaccination, I wrote (in Stevenson and Murphy's "Hygiene") that "it will not do to assume that throughout the world, from now to the end of time, small-pox will continue to rage epidemically unless prevented by universal vaccination," that "quite conceivably, small-pox rather than either scarlatina or measles, might be the next in order of the maladies to disappear from the civilised world," and that "when small-pox does go, the world will be rid of it, but while the bane remains with us, so also must remain the antidote." That is still my opinion. If we could be sure we were done with small-pox, then, indeed, vaccination should be abandoned not in the sophistical Leicester sense, but in reality, and the vaccination epoch would only remain in medical history as the time of the greatest success which had ever been achieved in the development of preventive medicine. Six or seven years ago it almost looked as if we might be approaching the disappearance of small-pox, but, unfortunately, there has now been a serious relapse into renewed prevalence, and we dare not yet dispense with the proved preventive.

Finally, my apologies are due to THE LANCET and its readers for occupying so much of its space in the first year of its second centennium.

---

[4] The Vaccination Question, p. 125.

THE EFFECTS OF RADIUM AND X RAYS UPON NORMAL AND CANCEROUS TISSUES.

THE admirable memorandum on cancer issued for the guidance of local authorities from the Ministry of Health in August last,[1] is to be supplemented, as occasion permits, by additional memoranda. The effects of radium and X rays upon normal and cancerous tissues is the subject dealt with in the first[2] of these supplemental monographs by Prof. W. S. Lazarus-Barlow.

Early Investigations and Conclusions.

In discussing early investigations and conclusions, he points out that from the empirical employment of X rays and radium, shortly after their discovery, in the treatment of cancer, the following facts emerged. It became clear that all varieties of cancer were not equally amenable to irradiation; also that X rays were not an entity, but that the rays were of different wave-lengths. Similarities between the rays from radium and X rays were noted immediately; differences were detected at a later date. At the present time each agent of radiation has its own more or less well-defined region of applicability, while sometimes a combination of the two is more effective than either used singly. It became clear that the action of radiations upon a group of cancer cells regarded as a new growth was not identical with that upon cancer regarded as a disease. Even though the duration of the disease were unmodified by treatment with X rays or radium, there was ample evidence that by their use the lot of the patient was often rendered more endurable. It became clear that whatever the degree of amenability of a growth to irradiation in the first instance, it became less responsive to irradiation on subsequent occasions. Lastly, it became clear that research was necessary upon the response of animal cells of all kinds to the varieties of radiation represented by soft, medium, and hard X rays, and alpha, beta, and gamma radiations from radium. More or less synchronously some attention was given to the biological properties of ultra-violet light, which consists of rays whose wave-length is greater than that of the softest X rays, and to the radiations from mesothorium, which compare with the rays of radium.

The casual nature of much of the pioneer work on the therapeutic use of radiations, together with the absence of fundamental data or precautions, much impaired its value. Later observations of the biological action of radiations are more systematic. Prof. Lazarus-Barlow divides these into investigations into their effects upon (1) normal cells and tissues; (2) cells of new growths, whether malignant (cancer) or non-malignant; and (3) cancer as a disease, where the radiations act on cancer cells intermingled with non-cancerous cells in an individual abnormal because the subject of disease. Owing to the lacunæ in our knowledge, it is impossible to consider X rays and radium rays separately, but there is reason to believe that much that is true for gamma rays of radium is also true for hard X rays, and that to some degree the same obtains for beta rays and soft X rays.

The Effects of Radiations upon Normal Cells and Tissues.

The nucleus, or cytoplasm, or both, may become dropsical or show isolated clear spaces (vacuoles) after exposure to irradiation; the rod-like chromosomes become irregular in shape, or granular, and divide irregularly; the framework of the nucleus, instead of showing an even arrangement, becomes collected into irregular heaps; the material formed by secreting cells is altered in quality or quantity; and the cytoplasm may undergo degenerative changes, chiefly mucoid. These are early changes. A day or two later, if the irradiation has been severe, dying and dead cells and fragments of nuclei or cells are seen, or a structureless mass of material may be the sole representative of the former living cells. If the irradiation has not been too severe, signs of recovery become manifest, and there is evidence that the damaged cells are being removed.

Changes such as those described, when occurring over a large area, lead to profound disintegration of tissue. This action must be remembered when deeply-seated abdominal new growths are treated by large doses of highly penetrating (hard) X rays. Before the great radio-sensibility of the intestine was recognised, cases occurred in which the medical practitioner, in his endeavour to irradiate sufficiently a cancer of the womb, damaged the intestine to such an extent as to be dangerous, and in a few cases fatal, to the patient. At the present time this danger is well recognised and guarded against.

It has been shown that cells and tissues manifest great differences in the degree to which they are affected by rays. The radio-sensibility of the lymphocyte of the blood and lymphatic glands is so great that an intense destruction occurs within an hour after a slight exposure of the animal to gamma rays; cells of the pancreas and thyroid, on the other hand, appear to be unchanged, even after severe irradiation; and brain cells are unaltered except under large doses. The behaviour of the same variety of cell differs in different animals. In the domestic cat, where fatty conditions are common in the kidney, gamma radiation leads to a profound fatty degeneration in the secreting cells of that organ, which has no parallel in any other species of animal hitherto examined. In the rat and in man voluntary muscle shows a marked proneness to degenerative changes of a fatty nature that does not occur in the frog, the rabbit, or the cat.

Differences of a like kind obtain even with cells commonly regarded as belonging to a single class. Endothelial cells lining blood-vessels show a few changes, while those lining certain of the large spaces of the body, or covering the stomach and intestines, show intense desquamation, and this in the same animal exposed to a single dose of gamma radiation.

Besides these injurious or destructive effects of radiations upon cells, in certain instances it has been found possible, by using minute doses of rays, to stimulate cells to increased rapidity of division. There is some evidence also that a muscle and nerve, under slight radiation, are stimulated, so that the muscle is rendered capable of putting out more work. The point is one of great importance in the radiotherapy of cancer.

Effects of Radiations upon Cells of Malignant and Non-Malignant New Growths.

Just as the lymphocyte has been found to be intensely radio-sensitive, so new growths built up of masses of lymphocytes, whether non-malignant (lymphoma) or malignant (lymphosarcoma), respond to irradiation by enormous destruction of the constituent cells. In the same way, the three varieties of carcinomata show alterations under radium or X rays analogous to those undergone by their normal prototypes. In the case of the sarcomata, the cells, like their prototypes, show general rather than particular changes after irradiation. It is undoubted that death of the cells and an intense mucoid degeneration take place, often over large areas.

It would appear that the effects of irradiating sarcoma cells depend rather upon the youth of the cells themselves, and the rapidity with which they attain full size and undergo division, than upon any peculiar radio-sensibility of that variety of cell as such. It is in accord with this view that wide differences obtain between the amenability to radio-therapy of the numerous different varieties of sarcoma.

As to endotheliomata, it has been noted above that the reaction of endothelium to gamma radiations appears to differ in different parts of the system. From observations made on the differences between the reaction of the lymphocyte and of the endothelial cell under identical radiation it would appear, not only that a radiation treatment which would be effective for a new growth built up of lymphocytes would almost certainly be ineffective for one built up of endothelial cells, but also that in the case of endothelial growths themselves amenability to radiation treatment would vary within wide limits. This is found to be true, some endotheliomata responding well to radiotherapy, others hardly at all.

---

[1] THE LANCET, 1923, ii., 479.

[2] Circular 476. H.M. Stationery Office. 1*d*.

Under irradiation the fibromyoma often shows remarkable diminution in size, but it is not yet certain whether the rays directly influence the tumour cells, or whether the effect is indirect and dependent upon ovarian changes resulting from participation of the ovary in the irradiation to which the tumour was subjected.

Effects of Radiations in Cancer as a Disease.

The necessity for effective treatment, not only of the central growth, but of the peripheral cancer cells, implies that in order to irradiate a small number of malignant cells great numbers of normal healthy cells of the part are coincidently irradiated, and to that extent damaged. The desideratum for all radiation treatment is maximal damage for the malignant cells and minimal damage for the body cells amongst which those malignant cells lie. It is usual to consider the normal tissue cells as being less radio-sensitive than the malignant cell but the margin is not great, and so much damage to normal tissues may accompany vigorous radiation of a new growth that an extensive intractable ulcer results. By some authors it is held that the poor results of radiotherapy when cancer has invaded bone depends essentially upon the coincident death of bone which the irradiation has brought about.

In yet another direction normal cells are involved when a case of cancer is undergoing treatment by radiations, particularly if the irradiated area be large. The blood circulating through the part is itself under irradiation, and lymphocytic blood changes, owing to the repeated access of fresh blood to the part, in course of time involve the entire circulating blood. In addition, the lymphatic glands may come under the influence of the rays, with the result that the total number of lymphocytes in the body suffers a diminution. Where the patient's blood was normal before irradiation the reduction of lymphocytic numbers may be relatively small, and return to normal takes place after an interval. But where the cancerous disease has already led to blood changes, irradiation, if sufficiently heavy for satisfactory treatment of the new growth, would lead to a grave augmentation of the blood condition and proportionate harm to the patient.

Many authors have described a "flaring-up" of cancer—particularly in distant parts of the body—after irradiation treatment, and have ascribed the phenomenon to operation of a stimulative action by minute doses of rays. Indeed, some authors have gone so far as to suggest that cancer may be originated in non-cancerous tissues in this way. As a matter of practical experience, it would appear that the risk of inducing cancer in a non-cancerous individual during treatment is negligible.

Prof. Lazarus-Barlow proceeds to discuss the various methods of applying radium and X rays in conjunction with each other and with surgery, and concludes as follows:—

"One thing is certain: the mental attitude of those most interested in radiotherapy has changed. Not only do they recognise that the radiations themselves, the cancerous conditions upon which they cause those rays to act, and the influence of the rays upon the normal tissues of the patient are far more complicated than was suspected at first, but also they envisage the radiation treatment in a fundamentally different way. At first the rays were regarded in the light of a specialised variety of caustic. As such they were inferior to many caustics in the surgeon's armamentarium. Then it was seen that cells vary in radio-sensibility, and a directly selective destruction of cancer cells was the goal, but was barely attainable by reason of the insufficient delicacy of our methods. Last of all, there has arrived in the minds of some authorities the conception of radiations as an agent whereby the cancer cells are altered in such a way that they evoke, within the patient's body and through the agency of his normal tissues, an increased production of some substance or substances antagonistic to themselves. The formation of such antagonistic substances within the patient, upon this view, characterises every case of cancer, and the course of the disease varies according to the degree in which they are present. In all but the rarest instances, however, they are insufficient, so that the cancerous process sooner or later gains and maintains the upper hand and leads to death. If by means of subjecting cancer cells to radiations one is able to imitate and enhance this natural process, the hope lies near that a production of antagonistic substances would be induced sufficient to hold the cancerous growth in check, then gain the upper hand, and ultimately destroy the cancer cells themselves."

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Inauguration of the Anti-Cancer Centre at Montpellier.

THE Minister of Hygiene and Public Welfare presided at the recent inauguration of the anti-cancer centre of Montpellier. Three similar provincial centres already exist at Bordeaux, Strasbourg, and Lyons, which are undertaking the specialised study and treatment of cancerous conditions. The Montpellier centre serves the district of the Languedoc and Roussillon, and is under the direction of Prof. Forgue, assisted by a carefully chosen staff, which includes Prof. Pech, Prof. agrégé Lamarque, for the physical causes of the disease, with Prof. Grynfeltt and Prof. agrégé Turchini for the study of pathological anatomy. Research work will be conducted in conjunction with the heads of the schools of medicine of Montpellier, and since the hospitals of the town have a large clientèle of patients suffering from cancer, it is to be expected that this centre will become one of the most active schools for the study and the treatment of malignant disease.

Shell-fish Control.

Since the introduction of preventive inoculation the clinical aspect of typhoid fever has changed considerably. In a paper read recently before the French Academy of Medicine, Mr. Courtois-Suffit gave a detailed study of 328 cases of typhoid and paratyphoid fever which had come under his observation during the last four years, and in which he expressed the opinion that the disease as it appeared at present was rarely due to water, but was to be traced chiefly to the consumption of infected food, mainly shell-fish, and in particular oysters. The Government has added what amounts to a corollary to this communication, by publishing a circular addressed to local authorities, with the object of controlling the trade in oysters and other shell-fish. Establishments trading in oysters will be listed in future, and only those which have been proved to be conducted on hygienic principles will be permitted to sell their wares. Shell-fish may not be sent from distributing centres unless they are accompanied by an official statement as to the cleanliness of their source of origin, while consignments of shell-fish which are not disposed of in a short space of time will be summarily seized and destroyed.

"Le Salon des Médecins."

The Salon des Médecins was recently opened for the first time since the war, under the presidency of Mr. Paul Strauss, Minister of Hygiene. In this salon are exhibited works of art created by contemporary medical men. The number and variety of these works of art are great, and include paintings, engravings, sculpture, pottery, and specimens of book-binding. The standard of art is high, and the salon is the more interesting because among the artists whose works are shown may be found the names of doctors who are known to lead busy professional lives, and who find, nevertheless, time to devote their leisure to the creation of beautiful things.

HOLLAND.

(FROM OUR OWN CORRESPONDENT.)

A New Disease Prevention Act.

A NEW law on infectious disease is about to be introduced; the laws now in force on this subject dating from 1872 and 1884. The preamble to the Draft Bill speaks of the old laws as "a queer, confused system of legislation." The municipalities were in charge of the execution of these laws and thus they ordered or refrained from ordering disinfection according to their own views or those of the advisory doctors (who in many cases were not too well-posted on the matter). The Government had no power to force them to act or to prevent them from doing so, if this was considered to be necessary. There was no unity of action and the epidemiological basis left much to be desired. According to the new law, management and control will be entrusted to the district medical officers of health (inspectors). The mayors must simply execute orders, but they can appeal to the head inspector. The theories of Charles Chapin (modes and sources of infection) are only slowly coming home to the Dutch medical men and epidemiologists. Not so long ago, in the case of diphtheria and scarlet fever, the room, bedclothes, the house itself, schoolrooms, &c., were disinfected, whereas in malignant cases expropriation and even destruction was under consideration—and here and there put into practice. A check will now be put on all these economic and epidemiological follies, which the Treasury can no longer afford. The strongest opposition comes from the side of the few sanitary engineers who are directors of sanitary and disinfection services, which services are more and more being brought under the public health service. People are more and more acknowledging the truth of Chapin's words, "Any scheme of preventive medicine which fails to take the carriers and the mild or missed cases into consideration is doomed to failure." Therefore, the Draft Bill opens the possibility of isolating carriers who are considered to be "a *special* danger for carrying the infection" and keeping them isolated until the infectious period is over. In few countries only has it been possible to make rules which encroach so severely upon social life and personal liberty. The Dutch Draft Bill goes even further and opens the possibility of prohibiting chronic typhoid bacilli carriers to work in trades which are specially liable to make possible the carrying of the infection—for example, handling foodstuffs, dairy business, waterworks. These people will be compensated in respect of loss of income if they are poor.

Vaccination.

So far the number of children who have not been inoculated has been small since they are not admitted to school unvaccinated, and education being compulsory only well-to-do people can afford to be objectors. Amongst its 3300 medical men Holland only counts two who give a certificate to every child to the effect that there are "objections on account of reasons of health." Conscientious objectors travel long distances to these anti-vaccination doctors. Political considerations have now induced the Government to insert in the Draft Bill a conscientious objection clause which enables objectors to get exemption after much less trouble, whereas further the signature of one doctor will be sufficient in order to get exemption on account of reasons of health. For the time being the Government want to give no more than 1 per cent. certificates of exemption, but it is likely that, when once an opening is made, the gap will become larger and larger. The medical world is very strongly opposed to this violation of the principle of compulsory vaccination, and it is still quite uncertain whether Parliament will pass the Government proposal.

Compulsory Notification.

The compulsory notification of the cases of infectious diseases mentioned in the decrees of the law is maintained, and this notification is extended to *suspected* cases. In this connexion it should be understood that tuberculosis and venereal diseases do not come under this law on account of the special social and moral aspects of the said diseases. Medical circles are almost unanimously opposed to compulsory notification in the case of tuberculosis and venereal diseases; as regards tuberculosis because no result is expected therefrom, and as regards venereal diseases because the confidence in the doctor would be shaken and many people would be kept back from putting themselves under treatment. Compulsory notification without compulsory effective treatment is regarded as useless.

Dangerous Infectious Diseases.

The Draft Bill discriminates between the dangerous exotic infectious diseases as cholera, plague, typhus fever, and small-pox, and the indigenous diseases as typhoid fever, scarlet fever, and diphtheria. Measles and whooping-cough will not come under the law, but malaria does come under it. For the dangerous exotic diseases compulsory hospital treatment is stipulated unless the family doctor is of opinion that the patient cannot be transported. In the latter cases the most rigorous isolation at home is ordered, a policeman or a soldier is to be placed before the door, who is not allowed to admit anybody but the doctor, the clergyman, and the notary. Such compulsory measures are also possible in case of the other diseases, but they will only be applied in special cases and if the family refuse to take the measures ordered for the prevention of carrying the infection.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of this Fund was held at St. James's Palace on April 1st, when, in the unavoidable absence of the Prince of Wales, the Earl of Donoughmore presided.

The Accounts for 1923.

Lord Revelstoke (the hon. treasurer), in moving the adoption of the accounts for the year which ended on Dec. 31st last, said that the conspicuous success of the Combined Appeal, which was opened in April, 1922, resulted in a total distribution of just over £418,000. The special distribution to hospitals through the King's Fund amounted to £365,000, of which £115,000 was distributed in 1923. The income of the King's Fund itself had benefited by the receipt of a considerable sum in dividends on the bequests of Lord MountStephen and Sir Thomas Sutherland. There was also an increase in annual subscriptions. The invested funds were increased by a further £175,000 received from the estate of the late Sir Thomas Sutherland, £11,000 from the estate of Mr. H. H. Wills, and £2000 in smaller sums. Other legacies amounted to £48,000, an amount rather smaller than that received in 1922, but £235,000 was distributed, an increase of £15,000 over 1922, the whole of this sum being provided out of the receipts for the year.

The motion having been seconded by Lord Mildmay of Flete, it was carried unanimously.

Improved Financial Position.

Lord Stuart of Wortley, chairman of the Management Committee, moved the adoption of the annual report of the General Council. This stated that in respect of income and expenditure, omitting the special distributions, the financial position of the hospitals had shown a steady improvement: the net aggregate annual deficit for 113 hospitals in London having been reduced from £383,000 for the year 1920 to £210,000 for the year 1921 and £174,000 for the year 1922. The total receipts for the year were £575,396 12*s.* 9*d.*, of which £145,113 1*s.* was received from the Hospitals of London Combined Appeal; £175,000 from the estate of the late Sir Thomas Sutherland; £2000 from the estate of the late Mr. Samuel Lewis; £48,398 17*s.* 5*d.* from other legacies; £12,767 15*s.* 8*d.* from gifts to capital; and £192,116 18*s.* 8*d.* from general receipts. The amount of the ordinary distribution was £235,000, an increase of £15,000 over 1922. The League of Mercy contributed £14,500, as against £15,000 in 1922. The total received by the Fund from the League since its foundation in 1899 was now £353,500, apart from the sums awarded by the League to institutions outside the area of the Fund's distribution. During the year the amount spent on the administration of the Fund was £8904 17*s.* 6*d.*, or £2 1*s.* 4*d.* per £100 of the total received (apart from the Combined Appeal), as compared with £8607 12*s.* 10*d.*, or 15*s.* 8*d.* per £100, in the previous year. The average yearly outlay in this respect for the whole period since the inauguration of the Fund had been £3635 2*s.*, the corresponding percentage of the receipts being £1 5*s.* 9*d.*, or just over 3*d.* in every £1 received.

Hospital Progress.

The adoption of the report was seconded by Sir Frederick Fry and carried unanimously. Sir William Collins then presented the unanimous report of the Ambulance Cases Disposal Committee, copies of which will be sent to the Voluntary Hospitals Commission, to the Minister of Health, to the police and ambulance authorities, and to the voluntary hospitals and infirmaries concerned. The reference of the Committee was limited to the method of ascertaining where bed accommodation was available for accident cases requiring admission as in-patients, and the suggestion that daily reports of vacant beds should be supplied to the police and ambulance authorities.

A message from the King congratulated the Council on the steady increase in the resources and annual grants of the Fund, and a letter from the Prince of Wales contained references to the progress of the hospitals. He stated that the gap between income and expenditure, taking all the London hospitals as a whole, was still closing year by year. For the year 1920, the very worst year of all, the gap, omitting all special distributions, was £383,000; for 1922 it was £174,000; while for 1923 it was too early to give the exact figures; but it was already clear that the hospitals, taken as a whole, had done better still. With the aid of exceptionally large legacies at two or three big hospitals, there was actually a net aggregate surplus, but, even without these legacies, the gap, for the year 1923, would be very nearly closed. This steady progress, going on now for three years without a break, was very hopeful, but it did not mean that the hospitals and the public could go to sleep in the belief that everything would come right of itself. The hospitals will still have to keep up their income at a figure nearly two and a half times what it was before the war, and they also had to be constantly adopting the latest improvements, and extending their work, in order to keep pace with the needs of the patients and the developments of medical science, necessary changes but often very expensive. The figures were only aggregate ones, and while steady general improvement was shown, there were a good many individual hospitals that still had deficits, and at some of these the financial position continued to give rise to serious anxiety.

The proceedings closed with a vote of thanks to the chairman.

Medicine and the Law.

The Harnett Case Appeal.

ON April 7th an application for judgment or a new trial on the part of Dr. C. H. Bond and Dr. G. H. Adam came before Lord Justices Bankes, Warrington, and Scrutton, sitting as a Court of Appeal. The Attorney-General, in opening the appeal on behalf of Dr. Bond, said that the real importance of the verdict in the action, tried before Mr. Justice Lush and a special jury, was this. It would be impossible henceforth to get a medical man to send anybody whom he believed to be a lunatic to an asylum, if the law was that, if a doctor acted negligently, he would be held responsible for all damages that flowed therefrom. Nobody being willing to take the risk of certifying, the country might be flooded with persons who ought to be in asylums. It was, he submitted, very difficult to see how the alleged negligent act of Dr. Bond could make him responsible for the negligence of others. The hearing is being continued. In this appeal, the solicitor to the Ministry of Health is acting for Dr. Bond, Messrs. Le Brasseur and Oakley for Dr. Adam, and Mr. W. E. Hempson for the British Medical Association.

The Public Authorities Protection Act.

In the King's Bench Division Mr. Justice Bailhache dismissed an action for libel brought by Miss A. B. Hope, formerly employed as "house mother" at Shirley Schools against Dr. J. B. Ridley, medical officer of the Bermondsey Guardians. In 1919, in his official capacity, Dr. Ridley made reports to the guardians to the effect that Miss Hope suffered from tuberculosis and therefore was not fitted for employment in the case of children. Miss Hope contended that these statements were untrue and libellous, and that she did not suffer from tuberculosis. Her writ, however, was not issued until a date considerably after her dismissal. The Public Authorities Protection Act, 1893, it was submitted by the defence, covered the case, as under it no action would lie against a public authority for any act done in the execution of a public duty, unless it were commenced within six months of the commission of the act complained of, and further that the Act protected in the same manner any person acting for a public body. It was submitted for the plaintiff that she had only recently been able to prove that she did not suffer from tuberculosis, and that it was then that the cause of action arose. Mr. Justice Bailhache held that Dr. Ridley was protected by the Public Authorities Protection Act and that proceedings had not been taken within six months as required.

Cancer of the Scrotum in a Mule-spinner: a Test Case.

At Ashton-under-Lyne County Court on April 4th, before Judge Mossop, a case was reopened of the utmost importance to the cotton trade in Lancashire. The point at issue is whether "epitheliomatous ulceration" or "epithelioma of the scrotum," contracted in the course of the worker's employment as a mule-spinner, is a disease for which compensation should be paid. The case came before the Stalybridge Court on Jan. 11th last and was then adjourned to enable certain particulars on the certificate to be amended.[1] Mr. E. Wingate-Saul, K.C. (for the applicant), in reopening the case, said the disease got its popular name from the fact that at one time it was prevalent among chimney sweeps. In 1920 it was discovered that it was a disease which was attacking large numbers of mule-spinners, of which there are 20,000 in the country. As a result of Home Office inquiries, in 1920, epitheliomatous cancer was added to the Act. On investigation it was found that out of a very large number of cases of epithelioma of the scrotum admitted and treated in the Manchester Royal Infirmary over 50 per cent. occurred in mule-spinners. The disease began on the anterior aspect of the left side of the scrotum. It was stated that when working a spinner "pieced" with his left hand and stood on his left foot, his left side at the groin coming in contact with the faller bar which was coated with mineral oil and the worker's pants became impregnated with the oil. Mr. H. H. Southam, F.R.C.S., who had made investigations on the disease in a cotton mill, stated that the scrotum came against part of the machinery which was covered with oil. Eighty per cent. of the cases in mule-spinners occurred on the left side and only 6 per cent. on the right side, by reason of the fact that the left side of the body came in contact with the faller bar. Under the conditions in which these men worked the scrotum was in a state of constant irritation from the mineral oil. The case under consideration, in his opinion, was absolutely due to the occupation. On an average there were seven cases of epithelioma of the scrotum per annum in the Manchester Royal Infirmary, and about half were mule-spinners. The hearing was then adjourned till May 22nd or June 20th, the date to be arranged later. From the annual report of the Operative Spinners' Amalgamation it is evident that the executive of the Amalgamation is giving careful attention to the subject. Numerous cases have been brought to light as a result of publicity. During the past year a joint committee representing the Amalgamation, the Federation of Master Cotton Spinners' Association, the Cotton Spinners' and Manufacturers' Association, and the Factory Department of the Home Office, drafted and issued a circular to operatives conveying certain simple measures of precaution.

[1] THE LANCET, Feb. 2nd, p. 252.

Thompson v. *New South Wales Branch, B.M.A.*

The Judicial Committee of the Privy Council recently dismissed the appeal of Dr. G. S. Thompson, of Sydney, New South Wales, against a decision of the Supreme Court of New South Wales. The Supreme Court had set aside a verdict for £2000 damages obtained by Dr. Thompson against the New South Wales Branch of the British Medical Association which had expelled him from membership, as having been "guilty of conduct derogatory to the honour and integrity of the medical profession" of the State and calculated to bring the profession into contempt and to injure the welfare and interests of the branch of the Association. The conduct complained of by the Association arose out of a case of recurrent insanity in a woman who, Dr. Thompson alleged, had been improperly confined in an asylum and improperly treated by medical colleagues. He had, in the view of the Supreme Court of New South Wales, cast serious imputations upon the conduct of members of the medical profession in regard to their treatment of the patient, founded upon his statements, which, if proved, would have warranted their own expulsion from the Association. In bringing his action Dr. Thompson based his claims for damages largely upon allegations of injury to himself through the rules of the Association forbidding its members to extend professional recognition to an expelled member, which, it was argued, operated in restraint of trade and were void. Lord Atkinson, who delivered the judgment of the Judicial Committee, pointed out that if the aims of the Association were to be carried out as to maintaining a high standard of professional conduct, there must be power to expel a member whose conduct offended against the honour and interest of his profession. If a body such as that which expelled him made a decision which it had jurisdiction to make, founded upon adequate evidence, that decision, in the absence of fundamental error, could only be impeached on the ground of corruption or bias or malice affecting the decision. In his judgment he had referred to the fact that Dr. Thompson had submitted himself to the rules of the Association in joining it originally.

Public Health Services.

INSURANCE MEDICAL SERVICE.

The Capitation Fee Settlement: Source of the New Funds.

AFTER all the winged words which have been uttered about raiding approved society funds and robbing insured persons of their "additional" benefits, it is interesting to note how the capitation fee of 9*s.* is to be provided. The source of the balance required to make up the fee from the sum of 7*s.* 3*d.* allowed by the Insurance Act to the 9*s.* granted by the Court of Inquiry is disclosed in the Bill introduced on March 31st by the Minister of Health (see Parliamentary Intelligence, THE LANCET, April 5th, p. 732). The dispute between the doctors and the approved societies as to who should pay the increased cost has been settled by the discovery of what may be called windfalls or unallocated reserves, on which the Government will draw for the purpose of increasing the medical benefit by the necessary sum. The increased cost, which is estimated at £1,350,000 per annum, is to be obtained from the unclaimed balance of insurance stamps and the excess interest earned on insurance funds. The first fund, which amounts to nearly £6,000,000, is due to the sale of stamps which since 1912 have never been claimed. The improvident people who bought these stamps have never joined an approved society, and hence no individual society can claim the money. The second fund is due to the fact that the Ministry was able during the war to invest the insurance funds at 6 per cent. and at that high rate of interest a fund accumulated which now stands at £2,000,000. The prescribed rate of interest being only 4½ per cent., there is a balance of 1½ per cent. to which the societies have no claim. The contention of the insurance medical service that the insurance funds were ample to provide what it considered an adequate capitation fee has been abundantly justified. The settlement is for three and possibly four years.

Ethical Committees in the Insurance System.

A new committee has been set up by the London Panel Committee for the purpose of carrying out the new duties allotted to panel committees under Article 28 (2) of the Medical Benefit Regulations (No. 2), 1923. This committee, styled the Ethical Subcommittee, is to consider all questions which come or are brought to the knowledge of the panel committee affecting the efficiency of the medical service. This is the first sign of the carrying out of an undertaking given by the insurance medical service to the approved societies that it would be responsible for the disciplinary control of the service to a much greater extent than heretofore.

Auto-Suggestion Outside the Range of Panel Practice.

At a recent meeting of the Lancashire Insurance Committee it was explained that a finding of the panel committee—to the effect that treatment of an insured person by auto-suggestion was beyond the competence of the ordinary practitioner and so outside the terms of his agreement with the insurance committee—did not imply expenditure on such treatment out of insurance funds. If the treatment was wished for in such cases and the medical man was willing to give it, it was treatment outside his agreement, and he could make his own terms with his patient with regard to it.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—The Ministry of Health announce that a Royal Charter has been granted for the incorporation of the Governing Body of the School, which is to be established as a result of the donation of $2,000,000 given by the Rockefeller Foundation for the purpose.

Correspondence.

"Audi alteram partem."

"BLIND CÆCOSTOMY."

To the Editor of THE LANCET.

SIR,—Mr. J. E. Adams's criticism of the operation of "blind cæcostomy" in your issue of April 5th will, I am sure, meet with considerable support among the younger surgeons, to whom falls the task of operating upon many of these cases of acute intestinal obstruction in old people. During two years of emergency operating at Guy's Hospital I developed an increasing aversion to this expedient, and this dislike is shared by my surgical contemporaries.

Mr. Adams has pointed out the occasional occurrence of a simultaneous obstruction of the large and small intestines by a growth, a condition which cannot be diagnosed without laparotomy, and in which a blind cæcostomy would not only be useless, but would allow the chance of a life-saving operation to slip by. A further disadvantage is that a second operation is always required if the patient survives, and that no data are available for the information of the patient or the guidance of the surgeon. Laparotomy allows us, if the growth be inoperable, to perform at once a permanent colostomy in the correct position, and if it be removable, to drain the intestine at a point which will best relieve the obstruction and facilitate subsequent resection. I do not believe that cæcostomy provides really efficient drainage of the colon except in its proximal half. I was deeply impressed by a case of acute obstruction due to a growth at the pelvi-rectal junction, which died from rupture of the bowel just above the site of obstruction four days after I had established a cæcostomy.

Where the obstruction is in the ascending or transverse colon cæcostomy is in any case the operation of choice, but the cæcum is often found distended almost to bursting-point with multiple linear ruptures of the peritoneal coat, and drainage is more easily, rapidly, and safely performed through a median incision into which the cæcum can be brought out and packed off, than through a small opening directly over it, which involves the risk of rupture and escape of highly toxic contents into the peritoneum. These cases die after the relief of the obstruction, in many instances, from a low-grade peritonitis due to the presence in the abdomen of infected fluid and blood which has exuded from the distended bowel. Blind cæcostomy will not avert this tragedy; laparotomy, on the other hand, allows gauze to be packed into the pelvis to mop up fluid while drainage is being established.

I do not believe that a rapid exploration under gas and oxygen carries greater risk to the patient than a blind cæcostomy, and it is undoubtedly a more surgical procedure.

I am, Sir, yours faithfully,
W. H. OGILVIE.

Wimpole-street, W., April 6th, 1924.

THE UNITED KINGDOM FREE HOSPITAL INSURANCE FUND:

A CORRECTION FROM KING EDWARD'S HOSPITAL FUND FOR LONDON.

To the Editor of THE LANCET.

SIR,—It has come to the knowledge of King Edward's Hospital Fund that a circular addressed to "Employers of Labour, Tradesmen, and Philanthropists" has been issued by the "United Kingdom Free Hospital Insurance Fund," 17, Ironmonger-lane, E.C. The second paragraph of the circular reads: "In a speech on 13th April, 1921, the Prince of Wales expressed a desire that the King Edward's Hospital Fund should be assisted through some means of insurance, and the present scheme has been outlined by the copyright holder of free insurance, the success of which has been phenomenal as evidenced by all the leading newspapers of to-day."

No such statement was made by His Royal Highness. The King's Fund published on April 13th, 1921, a report which mentioned insurance as a method that should be thoroughly explored. The King's Fund has since declared itself in favour of the general principle of schemes of mass contributions as suggested by Lord Cave's Committee, and this principle has already been adopted by various hospitals and by the Hospital Saving Association. But the scheme of the United Kingdom Free Hospital Insurance Fund is not one which the King's Fund could approve.

I am, Sir, yours faithfully,
SOMERLEYTON,
Hon. Secretary, King Edward's Hospital Fund for London.

Walbrook, E.C., April 7th, 1924.

THE PANCREAS AND DIABETIC METABOLISM.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 5th Prof. Horst Oertel has attacked the view that the islands of Langerhans are secretory units for purpose of an internal secretion and produce insulin. He has not brought forward any new work, but has restated the case against this view. He has, however, completely omitted all reference to the work of F. M. Allen (*Jour. Exper. Medicine*, 1920, xxxi., 593). Allen showed that when one-eighth of the pancreas of a dog was removed it was possible to produce definite changes in the β cells of the islands of Langerhans if the animal was overfed with either sugar or starch. The α cells of the islands and the cells of the acinous portion were quite unaffected. It would take too long to describe the experiments fully, but the work seems to show conclusively that there is a very close relation between the β cells and sugar metabolism.

I am, Sir, yours faithfully,
GEORGE GRAHAM.

Devonshire-place, W., April 5th, 1924.

NEGLECT OF THE EARLY SYMPTOMS OF INSANITY.

To the Editor of THE LANCET.

SIR,—A Royal Commission to study the administration of the Lunacy Laws being about to be appointed, the present seems an opportune occasion to draw attention to an important aspect of lunacy administration.

I have notes of 296 cases of suicide by persons sane and insane, and of murders by insane persons, including four cases where the crime was only attempted, reported in the press of England and Wales between Jan. 1st and March 13th, 1924—i.e., in 73 days, or one-fifth of the year. These figures, however, only give a rate of less than 1500 a year. Evidently they do not include more than one-third of the total number of suicides that have occurred, as statistics for the year 1921 show that 3759 suicides were reported in that year, besides 1187 other deaths by violence as to which open verdicts were recorded, many, if not nearly all, of which were due to suicide. Evidently two-thirds of the suicides occurring were not reported in the press, or were overlooked by my press-cutting agency. It is therefore probably justifiable to multiply my figures as regards suicides by three in order to arrive at the real facts.

The 296 cases reported may be classified as follows: Suicides, 274; joint suicides, 3; attempted suicide, 1; murders and suicides, 5; double murder and suicide, 3; treble murder and suicide, 1; suicides after attempted murder, 3; murders, 2; attempted murders, 2; attempted murder and attempted suicide, 1; murder and attempted suicide, 1. In all, 292 suicides and 17 murders, besides attempts, occurred in 73 days—

i.e., at the rate of 1460 suicides and 85 murders per annum. And, as stated above, the number of suicides was probably treble that number.

Signs of brain disorder, more or less definite, had been noticed *before* the crime in no less than 200 cases—i.e., in over two-thirds of the cases. Insomnia, great depression, pains in the head, moroseness, silence, "neurasthenia," fits, strange or changed demeanour, desire to die, and tiredness of life were among the commonest symptoms. But only 20 of these cases were reported to have been under medical treatment. Forty-three cases were reported to have been noticed to be very insane for some time previous to the crime, suffering from delusions or hallucinations, or behaving and talking quite insanely. Twenty-one were stated to have been formerly inmates of asylums.

The newspaper notices were usually very short paragraphs, and little information as to the circumstances of the case was furnished. If the official reports of the coroners' inquests were examined I have little doubt but that the existence of symptoms of brain disorder could be demonstrated in many others of these cases. In analysing these statistics the verdict of suicide during temporary insanity has been disregarded as evidence of insanity. Fifty of the cases of suicide had already shown their suicidal tendencies by previous attempts or threats or by expressing a desire to die.

Many of the causes to which the mental breakdown was attributed are very doubtfully correct. But in 69 cases the evidence appeared to show the cause fairly definitely as follows: Physical ill-health (various diseases), 17; excessive pain from cancer, &c., 3; influenza, 5; fracture of skull, 1; the result of air-raids (shock), 4; war (strain, disease, or injury), 9; drink, 1; domestic troubles, 8; love affairs, including seduction, 3; deaths of relatives, 7; financial difficulties, 3; poverty, 2; unemployment, 6.

The fact that the 200 persons mentioned in the statistics for 73 days as having shown signs of brain disorder before the crime, and perhaps 578 persons in the same period if we treble the figures of the suicides as suggested above, and doubtless five times as many in the whole year—i.e., nearly 3000 persons—were not placed under proper care in time to prevent their committing murder or suicide, seems to me extraordinary, and to suggest that there must be something seriously wrong with the Lunacy Laws or their administration.[1] Apparently the early stages of mental disorder, the condition in the majority of these cases, failed to receive adequate treatment. There is a very natural reluctance to proceed at once to the extreme measure of certification. Meanwhile the tragedy occurs, because short of certification no adequate steps can usually be legally taken, the law not allowing detention except after this drastic measure. The proposed Mental Treatment Bill is calculated to amend the present state of affairs. There are reasons, however, for thinking that no great improvement is to be expected until another radical change is made in procedure—viz., the withdrawal from the jury of the issue of insanity at all trials, and its reference to expert medico-psychologists.

The recent lunacy case, Harnett *v.* Bond and another, has intensified the already prevalent hesitation of doctors to certify insanity, especially in its earlier stages. Dr. H. Rayner points out in THE LANCET of March 15th that a private practitioner, not being a Government servant, should not be required to take any responsible part in carrying out an act prescribed by law, his duty consisting in advice as to the treatment necessary. He should not be held responsible for whatever action the authorities choose to take upon his opinion. The law, however, may object to accept certificates unless responsibility is cast on their framers. A solution of the question might be found by imposing the duty of certification on special medical officials, as it is an act prescribed by law. This proposal would also probably have the additional advantage that the official certifier would presumably be an expert medico-psychologist, as is not usually the case at present. The official would be responsible to his administrative superiors if he did not exercise due care.

The drawbacks of the jury system would, however, remain in criminal trials, in lunacy inquisitions and in civil actions.—I am, Sir, yours faithfully,

JOHN WARNOCK,
Late Director, Lunacy Division, Ministry
of the Interior, Cairo.

Addison-road, London, W., March 21st, 1924.

CERTIFICATES OF INSANITY.

To the Editor of THE LANCET.

SIR,—I apologise if I misunderstood Dr. Eager, but his first letter, following that of Dr. Rayner, did seem to suggest that professional etiquette forbade our revealing to certified patients the reasons for their confinement. In his letter last week he seems even to emphasise this position, for he says, "In other words, are they [certificates] not of the nature of confidential statements furnished by one doctor to another?" Dr. Eager refers to Dr. Macnamara's letter, which pleads for secrecy on therapeutic grounds, but does not indicate what classes of cases would be harmed nor what harm they would suffer through being shown their certificates. Dr. Macnamara appears to have in mind insanity with gross derangement of intellectual functions; but no one proposed to show these patients their certificates. There is, as he says, "no point in it," but equally there would be no harm. The cases that here concern us are the hypomanics and paranoiacs, and I should be interested to know precisely how Dr. Macnamara thinks these diseases would be aggravated by the procedure in question. Emphatic generalities are not sufficient; we want definite and reasoned objections, for it seems quite probable that an attempt might be made to enact that all patients must be shown their certificates. Even from the therapeutic point of view it seems to me that the balance of advantage is on the side of non-concealment.

I am, Sir, yours faithfully,
Perth, April 6th, 1924. IAN D. SUTTIE.

PREPARING HANDS AND GLOVES FOR OPERATION.

To the Editor of THE LANCET.

SIR,—In 1906, when the use of rubber gloves in surgery was becoming common in this country, I tried the effect of mechanically cleansing them under running water, the gloves being on the hands. After dipping the fingers into a mixture of pus obtained from a dental abscess and from an ischio-rectal abscess and thoroughly soiling them, I held them under a rose tap and worked the fingers against each other until all apparent trace of pus had disappeared. I then rubbed the fingers on agar plates. No growth was obtained with either the smooth or the crenated gloves, but after opening an abscess in a fat patient I found growth occurred. I tried this again but could never be sure of getting a sterile surface in a crenated glove covered with fat and pus, although the growths were few and small. Whether the fat dissolved the rubber or merely clung to it and anchored the bacilli I do not know. I have not repeated the experiments with a modern glove, but have frequently relied on them especially for examination and dressing.

The first thing we did on moving into our operation theatre at the 43rd General Hospital in Salonika was to improvise a rose tap and elbow-piece. In handling a large number of heavily infected cases in rapid succession with a small staff and overworked sterilising appliances the risk of trusting to mechanical cleansing by running water seemed to me to be far less than that involved in waiting for possibly more certain measures. The method is very useful also in dealing with a large complicated wound in which only partial excision as against complete excision is possible. The great saving of time and labour and the reasonable certainty of the surface of the rubber being sterile make all exact experiments to establish the degree of risk of great importance. The method will appeal to those who, like myself, prefer to have the interior of the glove dry, and not to use a glove put on full of water. Surgically the factors of new or old rubber, fat, mucus, fæcal material, and dead epithelium (which tends to stick to rubber) come in. Ether, petrol, turpentine, and other substances in common surgical use are solvents of rubber in greater or less degree. Different organisms may cling in unequal degree to the surface of the rubber.

---

[1] While 22,740 persons were certified and treated in 1922 under the laws, nearly 3000 a year do not receive proper treatment and suffer violent deaths in consequence, besides killing their neighbours in many cases.

The trials suggested themselves to me when listening to Klein describing his experiments on testing oysters for typhoid. He washed the shells in a bath of running water. Anyone who has experimented with the dilution of coloured solutions knows how important it is to completely empty the bath of solution—that is to say, several complete emptyings and fillings yield a less coloured, final result than is obtained for the same added volume if merely run in and allowed to run out continuously. Washing gloves under a running tap approximates to the ideal in this respect as the volume held on the surface of the glove is relatively small. I am, Sir, yours faithfully,

Aberdeen, April 4th, 1924. G. H. COLT.

INSULIN BY THE SKIN AND MOUTH.

To the Editor of THE LANCET.

SIR,—With reference to the annotation with this heading in your issue of Feb. 23rd I should like to ask whether insulin has ever been tried by the rectum. If not, perhaps readers who are in a position to do so would try this route, giving watery or oily suspensions of small bulk after an evacuation of the lower bowel, and publishing their results.

I am, Sir, yours faithfully,
H. H. KING,
Major, I.M.S.

Central Research Institute, Kasauli,
March 20th, 1924.

Obituary.

FREDERICK WILLIAM HIGGS, M.D., M.R.C.P. LOND.

Dr. F. W. Higgs, medical officer to the Ministry of Health, whose death on March 26th we regret to announce, was born on May 18th, 1881, the eldest son of Dr. Augustus W. Higgs, of Chelsea. He entered St. George's Hospital in August, 1898, where he was a successful student and took several prizes, including the William Brown Scholarship and Exhibition. Qualifying L.S.A. in 1904, he held in succession the usual junior house appointments at the hospital and proceeded to the M.B., B.S. Lond. in 1906, gaining the M.R.C.P. in 1907, and his M.D. in 1911. After giving up residence at St. George's he held several of the junior appointments in the medical school, such as assistant curator of the museum and demonstrator of materia medica. He was one of the most efficient medical registrars that the hospital has had of late years, and on more than one occasion he undertook some of the duties of the dean or warden of the school as it was then termed, while he was for a short period temporary assistant physician to the hospital. On starting practice Higgs specialised in diseases of children and was for a time physician to the Belgrave Hospital for Children. He was a capable clinician, a careful and conscientious physician, and it was to the regret of his friends that he decided, about the year 1909, to give up consulting for departmental work, for which, it is true, his orderly and methodical mind was peculiarly adapted. He joined the Public Health (Education) Department of the London County Council and was for some years in charge of one of the London districts. On his return from the war he became a medical officer to the Ministry of Health.

From the days of his house surgeoncy Higgs had been keenly interested in military matters, and as major in the R.A.M.C. (T.F.) he was called up on active service at the outbreak of the war, but on account of an old cardiac lesion he was not allowed to go to the front with his casualty clearing station, in the details of the organisation of which he had taken endless pains. In 1915 he was considered fit for active service and served in France for three years, was twice mentioned in despatches, and received the C.B.E. Early in 1920 he was gazetted as colonel A.D.M.S., 2nd London Division. He had recently been appointed county director for London on the Central V.A.D. Council. Higgs took up the livery of the Society of Apothecaries in 1919. A keen Freemason, he had passed the chair in the Lanesborough Lodge in connexion with St. George's Hospital, in which lodge he had been initiated in 1907.

The funeral service took place on March 29th and was conducted with full military honours.

Dr. Higgs married Dorothy, daughter of Dr. J. Walter Scott, of Chandler's Ford, Hants, and late of Tulse Hill, and had two daughters; to his family and to his parents we extend our sincere sympathy in their bereavement.

FREDERICK WOMACK, M.B., B.Sc. LOND.

Dr. Womack's death on March 11th removes one who made it his life work to make ancillary science acceptable to the medical student, a not inconsiderable task in these days. Born in 1857, Frederick Womack entered St. Bartholomew's Hospital at the age of 21, and remained associated with the hospital until the time of his death. He graduated B.Sc. honours in 1881 and M.B. Lond. in 1884. In the former year he was appointed teacher of mathematics to the matriculation class which was then held and became demonstrator of what was still known as "natural philosophy." In 1892, when a separate lectureship in physics was instituted, Dr. Womack became lecturer. He was also lecturer in physics at Bedford College for Women, consultant toxicologist to a number of London coroners, and found time to lecture for the University Extension. He was an ardent national volunteer, and during the war visited France to lecture to troops in rest camps. Dr. Womack's attractive personality gained him a wide circle of friends, to whom his ability in music and story-telling made appeal. His long and painful illness was borne with fortitude.

WILLIAM ALFRED WILLS, M.D., F.R.C.P. LOND.

Dr. W. A. Wills, consulting physician to the Queen's Hospital for Children, died at Rotherhill, Midhurst, on April 1st, aged 61. Born in 1863, he was a son of the late Sir Alfred Wills, who had a distinguished career at the Bar. Dr. Wills received his professional education at Westminster Hospital, and qualified M.R.C.S. Eng. in 1884. A year later he took the degree of M.B. Lond. with honours. In 1890 he proceeded to the M.D. Lond., and in 1902 he was elected a Fellow of the Royal College of Physicians. He was for some time physician at St. Marylebone General Dispensary and at Westminster Hospital, and at the latter was the author of the annual reports of the Medical Register of the Hospital from 1888 to 1892. He was afterwards appointed physician at what was then called the North-Eastern Hospital for Children. During his long career of activity in London he found time to contribute many and various articles to medical literature. In 1897 a monograph by him on Diseases of the Mouth appeared in Allbutt's "System of Medicine," and in 1901 he wrote on Mountain Sickness in Quain's "Dictionary of Medicine." Some of his work appeared in THE LANCET in 1896 and in

1901. On his retirement from professional activities he settled down in Midhurst, Sussex, where he identified himself with all branches of public work. He became a member of the West Sussex County Council, was placed on the Commission of the Peace for West Sussex, and was one of the justices appointed under the Lunacy Act as a visitor to asylums. Nursing work always claimed his enthusiastic support, and by his death the West Sussex Nursing Association has lost one of its valued helpers and advisers. Dr. Wills was a man of generous nature who made many friends, not least among the poor. Of his recreations, the chief was Alpine climbing, and he acted as secretary of the Alpine Club, of which his father was one of the founders. His funeral, which was largely attended, took place at Stedham on April 4th.

WILLIAM HENRY COATES, M.B. DURH., M.R.C.S. ENG.

WE regret to record the recent death, at his residence, Bleak House, Patrington, Holderness, of Dr. W. H. Coates, one of the best-known medical men in the East Riding of Yorkshire. Born in York over 60 years ago, his public record as physician, surgeon, barrister, county councillor, and administrator must be well-nigh unique. He studied at the University of Durham, where he took the M.A. and M.B. in 1888, and where he acted as a demonstrator of anatomy, and later at the London Hospital he was a demonstrator in histology. In 1889 he became M.R.C.S. and L.R.C.P. Lond. In his spare time he qualified as a Barrister-at-law, and was called to the Inner Temple in 1899. His professional appointments were many and varied, and included that of medical officer of health for Patrington, public vaccinator, chemical analyst, medical officer to Linsdale's Hospital, certifying factory surgeon, and surgeon to Trinity House. He was also a member of the North Sea Fisheries Commission, and consulting surgeon to Lloyds and the U.S.A. Consulate. During the war he was medical officer for two hospitals and several military camps in South Holderness with 1800 men in his charge, and he acted as local food and fuel controller. He was interested in politics, and on two occasions he refused invitations to be nominated as a candidate for Parliament. In his early years in London he had many friends amongst journalists, and was on occasion an active worker and writer of leaders and a dramatic critic. He also took a keen interest in chemical matters, and in 1891 published a book entitled "Food: Its History and Adulterations," and in 1899 contributed an article to THE LANCET on Poisoning by Mercuric Chloride.

Dr. Coates was a man of brilliant and versatile powers, and his death will be a loss to South Holderness, where he had many friends.

EDWIN CLAUDE TAYLOR, M.D., M.S. LOND., F.R.C.S. ENG.

Dr. Claude Taylor, who died at Birmingham on March 29th in his fifty-fourth year, was a man of very high academic attainment who deliberately chose to go into general practice as a form of social service. He was educated at Caius College, Cambridge, passing on to Guy's Hospital for his clinical work. After qualifying in 1894 he held appointments as house surgeon and resident obstetrician at Guy's and assistant medical officer at the London Temperance Hospital. During this period he took in succession the M.D. Lond., F.R.C.S. Eng., and M.S. Lond. In 1898 he settled in Hampstead, where he acquired a very large general practice, the claims of which did not prevent him finding time for work in connexion with child welfare and temperance. He was visiting medical officer to the Hampstead Infirmary, where he originated the idea of the nurses being able to qualify for their full certificate with Poor-law hospital experience. During the war the infirmary became a military hospital to which Dr. Taylor acted as visiting physician. Owing to failing health he gave up practice in the autumn of 1922 and sought on the Riviera a renewal of vigour which unfortunately did not return. At a memorial service held at the Friends' Meeting House, Bourneville, on April 2nd, Sir George Newman said: "The love of a medical man for his craft must always be associated with love of humanity and that Dr. Taylor had in an exceptional degree; and so he became a great doctor, a great physician, and a good surgeon." Mr. W. McAdam Eccles writes: "As one who had a very close professional and friendly relationship with Dr. Claude Taylor, I am proud to bear testimony to the fine example he set. He was untiring in his care of patients, skilled in diagnosis, sound in treatment. He was ever ready, while holding some advanced views on certain matters of medical politics, to discuss and argue differences with an open mind and restraint. He was keen on the moderate and scientific view of the alcohol question, and did much to help forward the dissemination of sane knowledge thereon. His loss will be felt widely, not least by those with whom he was professionally connected."

Dr. Taylor married Miss Huldah Southall, of Birmingham, and had five children, of whom two sons are following the medical profession. Much sympathy is felt with his family in their loss.

THOMAS RIDGE JONES, M.D. ABERD., M.R.C.S. ENG.

Dr. Ridge Jones, whose death took place on April 4th after several years of ill-health, was intimately connected with the Victoria Hospital for Children in London for over 40 years. A son of Thomas Jones, of Rhyl, North Wales, he was born in 1840, and obtained his early education at the Liverpool Institute. He proceeded to the study of medicine at the medical colleges of Middlesex and St. George's Hospitals. As a student Dr. Jones had a brilliant career, and whilst at the Middlesex Hospital he gained the Governors Prize "for the most distinguished student at the Middlesex Hospital." He qualified L.S.A. in 1860 and M.R.C.S. Eng. in the following year. Continuing his medical studies, he went subsequently to Aberdeen University, where, in 1869, he graduated M.B. and in the following year gained his M.D. His first appointment brought him back to London to be resident medical officer at St. George's Hospital, and after filling this post for 11 years he joined the staff of the Victoria Hospital for Sick Children which had recently been founded. To Dr. Jones's support and service the Victoria Hospital owes not a little of its present prosperity, and during the 26 years in which he acted as hospital physician he saw many improvements and extensions take place. At the termination of his 26 years' service as acting physician to the hospital he was appointed as consultant. Of Dr. Jones's contributions to medical literature may be mentioned a study of an outbreak of small-pox which occurred in St. George's Hospital and published in the hospital reports. He was specially interested in the study of cerebral hæmorrhage, of which malady he himself was the victim some three years ago and which finally caused his death. Dr. Jones had a large consulting practice apart from his hospital duties; the care of children was always his first interest. He never actually retired, but latterly was obliged to lead a less strenuous life, although his faculties remained unimpaired. In 1876 he married Ruth, daughter of Dr. Joseph Ridge. To his widow and family we extend our sincere sympathy.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society will be held to-day (Friday) at the Miller General Hospital, Greenwich, at 8.45 P.M., when Mr. P. P. Cole will give a communication on the Surgery of the Face and Jaws. The President, Dr. E. G. Annis, will occupy the chair.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Protection Against Lead Poisoning.

ON April 3rd Mr. HENDERSON (Home Secretary) presented a Bill "to make better provision for the protection against lead poisoning of persons employed in painting buildings." The Bill was read a first time.

National Health Insurance (Cost of Medical Benefit) Bill.

The National Health Insurance (Cost of Medical Benefit) Bill was considered by Standing Committee "C" of the House of Commons on Tuesday, April 8th. Mr. A. SHORT presided.

Mr. HARVEY moved an amendment to delete paragraph (*b*) of Subsection 2 of Clause 1 in order to elicit from the Minister of Health some assurance that the Government would see that the interests of those who did not belong to approved societies were adequately protected.

Mr. WHEATLEY said that if he accepted the amendment it would upset the scheme of the Bill. But there was no danger at all of any insured people suffering from the scheme of finance contained in the Bill. The Government had gone into the matter very carefully and they found that after making all essential reserves—and even generous reserves—they would have plenty of money for the purpose.

The amendment was by leave withdrawn.

On the question that the Bill be reported without amendment to the House,

Sir KINGSLEY WOOD asked the Minister of Health if he would explain to the Committee the exact position in regard to the setting up of the Royal Commission to examine the whole system of national insurance.

Mr. WHEATLEY said that the negotiations for setting up the Royal Commission were very well advanced. He had submitted the terms of reference to the approved societies and the doctors and they had agreed to them. They had now to be submitted to another body before it would be proper to report them to the public, but he anticipated no difficulty in the matter. With regard to the personnel of the Commission hon. Members would realise that he was not alone responsible for determining that. He had to negotiate with the people interested and receive the authority of the Government as a whole. But there again he did not think there would be any difficulty, and he anticipated no delay.

Sir KINGSLEY WOOD: Will the personnel include representatives of the various interests affected?

Mr. WHEATLEY: You are raising a point which is one on which I might very easily slip.

Mr. PERRY suggested that the Commission ought to consider whether the method of stamping cards should be continued under any revised scheme of national health insurance administration.

Sir W. JOYNSON-HICKS urged that the Commission should be an impartial body. When he was Minister of Health he received the consent of a very well-known man, not of his own political persuasion, to occupy the position of chairman. It was of great importance that the tribunal should command the confidence and support of the House of Commons and the country generally.

Mr. FALCONER said that there was a great danger that people would be put on the Commission who were most excellent members of the community, but who had no real knowledge of the problems of national insurance. Under those circumstances the work of the Commission would be an almost hopeless one. He agreed that the chairman ought to be a man outside any of the interests affected.

Mr. B. TILLETT said that he hoped that the Minister would not appoint a Commission of experts.

Mr. MASTERMAN pointed out the desirability of urging the Commission to report as promptly as possible.

Lt.-Col. FREMANTLE said that while he was not qualified to speak on behalf of the doctors, he believed that their position was this: the medical profession would not wish to be represented on the Commission if it was decided that it should not be a Committee of experts, but they would raise strong objection if, after that decision had been taken, representatives of approved societies and so forth were included. The doctors hoped that, whether experts were to be placed on the Commission or not, the profession would be treated fairly and that the whole matter would be given a considered and impartial judgment. If that were so, the doctors had perfect confidence in the justice of their case where it came into conflict with the views of other persons.

Mr. WHEATLEY, replying to the points raised, said that he could not promise that the Commission, however it was selected, would report in a very short time. The question which it would have to consider was a very complicated one and the inquiry would take time. As regarded the suggestions which had been made he would give due weight to all of them, but the Committee must recognise that a storm would break around his head immediately he had appointed the Commission, no matter what course he adopted.

The Committee stage of the Bill was concluded.

HOUSE OF LORDS.

TUESDAY, APRIL 8TH.

Therapeutic Substances Bill.

Earl DE LA WARR, on behalf of the Ministry of Health, moved the second reading of the Therapeutic Substances Bill, a measure to provide for the regulation of the manufacture, sale, and importation of vaccines, sera, and other therapeutic substances. He said the measure was non-contentious.

The substances to which the Bill applies are vaccines, sera, toxins, antitoxins and antigens, salvarsan (dioxy-diamino-arseno-benzol-di-hydrochloride) and analogous substances used for the specific treatment of infective disease; preparations of the specific antidiabetic principle of the pancreas known as insulin, and preparations of the posterior lobe of the pituitary body intended for use by injection.

Clause 1 provides that no person shall manufacture for sale any of these substances unless he has a licence granted by the Minister of Health, the Scottish Board of Health, or the Minister of Home Affairs for Northern Ireland. Applicants for licences must satisfy the licensing authority that the conditions under which the therapeutic substances are to be manufactured comply with the regulations under the Act. Licences may be revoked for failure to comply with the conditions attaching to them, and the regulations under the Act as to standards of strength, quality, and purity. Nothing in the section shall apply to the preparation by a registered medical practitioner of the substances in question. Clause 3 places restrictions on the importation of such substances into Great Britain or Northern Ireland. Clause 4 provides for the establishment of a joint committee consisting of the Minister of Health (chairman); the Secretary for Scotland; and the Minister of Home Affairs for Northern Ireland; and also an advisory committee to assist the joint committee, one member appointed by the Minister of Health, who shall be chairman, one by the Scottish Board of Health, one by the Minister of Home Affairs for Northern Ireland, one by the Medical Research Council, one by the General Medical Council, and one by the Council of the Pharmaceutical Society of Great Britain. Clause 5 gives power to the joint committee, after consultation with the advisory committee, to make regulations for various purposes.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 2ND.

Inquiry into Lunacy Laws.

Mrs. WINTRINGHAM asked the Minister of Health what interests would be represented on the committee appointed to inquire into the Lunacy Laws.—Mr. GREENWOOD (Parliamentary Secretary to the Ministry of Health) replied: It is not intended that the body appointed to inquire into the Lunacy Laws shall be composed of representatives of interests. The aim of the Government will be to set up a small impartial body of persons qualified to deal with the legal and medical issues and the questions of public policy involved in this inquiry.

Village Settlements for Tuberculous Men.

Mr. PHILIP OLIVER asked the Minister of Health which village settlements for tuberculous ex-Service men had been allotted grants to meet the cost of the erection of cottages and the amounts of such grants; why no grant had been made to the East Lancashire tuberculosis colony at Barrowmore; and would he consider the making of such a grant in the immediate future.—Mr. GREENWOOD replied: The village settlements in question are at Papworth and Preston Hall, and £10,000 has been allotted to each for this purpose. As regards Barrowmore, my right hon. friend understands that at the suggestion of one of his predecessors the Joint Finance Committee of the British Red Cross Society and the Order of St. John of Jerusalem have voted the sum of £10,000 to the East Lancashire Tuberculosis Colony in order that cottages may be provided there for tuberculous ex-Service men. My right hon. friend has called for a report as to the present position at Barrowmore and the need for any further development.

Local Tribunals under Midwives Board.

Mr. SHORT asked the Minister of Health whether, seeing that registered midwives who contravene the regulations are summoned to appear before a tribunal in London, entailing great expense to the person so appearing, he would consider the appointment of area tribunals to deal with such cases.—Mr. Greenwood replied: The duty of deciding upon the removal from the roll of midwives of the name of any midwife for disobeying the rules and regulations of the Central Midwives Board, or for any other misconduct, is imposed by Statute upon that Board, and my right hon. friend does not think it would be possible to arrange for such cases to be dealt with by area tribunals. Many disciplinary cases of a minor character are dealt with locally by the local supervising authorities. I may add that the Central Midwives Board are empowered to defray the expenses incurred by any midwife who may be required to appear before them in her own defence.

Government Lymph Establishment at Hendon.

Mr. Black asked the Minister of Health how many calves at the Hendon Institute were under vaccination at the same time, and what was the source of the lymph with which they were vaccinated.—Mr. Greenwood replied: The number of calves vaccinated week by week at the Government lymph establishment varies according to the demand for lymph, the supplies in stock, and other circumstances. The lymph at present used at this establishment is a strain of lymph obtained many years ago which has been carried on by repeated transference from calf to calf.

Medical Benefit for Dependents of Insured Persons.

Mr. Nixon asked the Minister of Health if he would arrange that the question of providing medical benefit under the National Health Insurance system for the wives and children of insured persons be inquired into by the Royal Commission which he proposed to set up.—Mr. Greenwood replied: My right hon. friend has no doubt that the subject referred to by the hon. Member will be included amongst the matters which will come under the consideration of the Royal Commission.

Cancer in Birmingham.

Mr. Alfred T. Davies asked the Minister of Health whether his attention had been directed to the appointment of a special committee by the Birmingham City Council to inquire concerning the prevalence of cancer in the city, the facilities for treatment of the disease, and the steps which might usefully be taken by their council to help cancer sufferers; whether similar committees had been appointed in other counties, cities, or towns; whether he approved of such local committees, and would give them encouragement where possible; and whether he would direct the attention of county, city, and town councils and other public bodies to the action taken at Birmingham.—Mr. Wheatley replied: The answer to the first part of the question is Yes. My Departmental Committee on Cancer is in touch with the medical officers of health of several other towns with a view to the prosecution of similar inquiries either through special committees or otherwise, as may be most suited to the area concerned. The formation of such local committees has my cordial approval, and I may refer to the suggestions on this point contained in the memorandum on cancer issued by my predecessor to all local authorities in England and Wales in August of last year.

Tuberculin-tested Milk.

Mr. Mills asked the Minister of Health what number of licences had been granted during each of the years 1920, 1921, 1922, and 1923 to producers, to retail distributors, and to wholesale distributors of milk, to use each of the following designations: Certified, Grade A tuberculin tested, and Grade A pasteurised.—Mr. Greenwood replied: According to the records in the department, the numbers of licences in operation at the end of each of the years 1920–23 were as follows:—

—	1920.	1921.	1922.	1923.
Certified—				
Producers	9	23	41	55
Shops	10	49	170	598*
Grade A (tuberculin tested)—				
Producers	11	15	22	46
Bottling establishments ..	8	11	17	26*
Shops				118*
Grade A—				
Producers	—	—	—	50*
Bottling establishments ..	—	—	—	24*
Shops	—	—	—	115*
Pasteurised—				
Pasteurising establishments ..	—	—	—	57*
Shops	—	—	—	107*

Up to the end of 1922 the special designations were "Grade A (Certified)" and "Grade A." The conditions applying to these designations were nearly the same as those now applying to "Certified" and "Grade A (Tuberculin Tested)" respectively. The licences whose numbers are marked with an asterisk were issued by local authorities and the numbers given may possibly not be quite complete.

Health Insurance Administration.

Sir Rowland Blades asked the Minister of Health the actual amount expended on administration and other costs of working by the approved societies in the year 1922; the actual amount expended on administration by the National Health Commission in the same year; the amount of any other expenditure incurred in the administration of the Act by the insurance committees or other bodies, excluding payments to medical practitioners; and what rates these expenses are to the actual contributions from all sources, save Government grants in aid, received during the year.—Mr. Wheatley replied: The amounts expended on administration of National Health Insurance in England and Wales in the year 1922 were as follows: Approved societies, £2,913,000; Ministry of Health and other Government departments, including National Insurance Audit Department and Government Actuary's Department, £1,010,000; insurance committees, £378,000. Excluding Government grants in aid received during the year from the actual contributions and expenditure of Government departments on administration, the ratio of administration expenditure to contributions from all sources is 12¾ per cent.

Joint Advisory Committee on Milk Production.

Mrs. Wintringham asked the Minister of Health what interests were represented by the various members of the joint committee appointed to advise on matters concerning the production, handling, and distribution of milk and dairy produce.—Mr. Greenwood replied: The bodies represented on the committee are the National Farmers Union, the National Federation of Dairymen's Associations, the Parliamentary Committee of the Co-operative Congress, the National Association of Creamery Proprietors and Wholesale Dairymen, the National Clean Milk Society, and the London and Provincial Master Dairymen's Association.

THURSDAY, APRIL 3RD.

Richmond and Orpington Hospitals.

Mr. Somerville Hastings asked the Minister of Pensions the number of empty beds in Richmond Park and Orpington Hospitals respectively, and whether and how he proposed to utilise these hospitals in future.—Mr. F. O. Roberts replied: The numbers are 36 and 67 respectively, all of which are, however, allocated to patients about to commence treatment. It may not be necessary to retain the hospital at Richmond Park after next autumn, but there is at present no prospects of the accommodation at Orpington ceasing to be required by my department.

Ex-officer's Removal to Mental Hospital.

Mr. Costello asked the Minister of Pensions whether he received a communication, dated Feb. 29th, 1924, from a pensioned ex-officer, at that time an inmate of Haydock private asylum, Newton-le-Willows, Lancashire, in which that officer asked for a medical examination and inquiry into his case with a view to showing that he was perfectly sane; what was the reason why this officer was, in October, 1923, summoned to a Ministry of Pensions hospital at Knotty Ash, Liverpool, in order to proceed to the Isle of Wight for convalescence, and that instead of that he was taken to the above-named asylum without his wife or any of his relatives being informed of his removal thereto; why was he detained as a lunatic until March 4th, 1924, upon which date he escaped and, after remaining in seclusion for the statutory interval of 14 days, recovered his freedom; is he aware that this officer was awarded 100 per cent. disability for severe wounds and that the pension is now being held up, if not entirely stopped; and would he cause inquiries to be made with a view to taking action for remedying these matters.—Mr. F. O. Roberts replied: I regret to say that this officer, who had been awarded disability retired pay at the maximum rate, had, after admission to Knotty Ash Hospital, to be transferred, under an urgency order to a mental hospital. The proposed convalescent treatment could not therefore be proceeded with. As the hon. Member states, the officer escaped from the mental institution, and as this happened about the time of receipt of the letter referred to in the first part of the question, the medical examination he asked for could not be made. With regard to the last part of the question, whilst the officer was in the mental hospital arrangements were made for payments due to him to be made to his wife, but in the present circumstances payment will be made to him direct.

Military Hospital at Craigleith.

The Earl of Dalkeith asked the Minister of Pensions whether it was the intention of the Government to close down the military hospital at Craigleith; and what were their reasons for doing so.—Mr. F. O. Roberts replied: In view of the decline in the requirements of my department for accommodation for in-patients in Scotland I am making arrangements to give up this hospital next autumn.

Medical Evidence in Final Pension Awards.

Sir ROBERT ASKE asked the Minister of Pensions what kind of evidence would be accepted by him as showing that an award was erroneously declared final; whether medical evidence was essential for this purpose; and whether he would pay the applicant's doctors' fees for examination and report as to errors in awards.—Mr. F. O. ROBERTS replied: The question whether an award was made final in error owing to incorrect diagnosis will be determined on the results of examination by a Special Medical Board of the Ministry. Ordinarily it is anticipated that such cases, which are not numerous, will be discovered in the course of medical treatment by the Ministry.

MONDAY, APRIL 7TH.

Medical Services in Bengal.

Lieut.-Colonel HOWARD-BURY asked the Under-Secretary of State for India whether he was aware that owing to the reduction in the estimates for the educational and medical services in Bengal, passed by the Bengal Legislative Council, the Government were now forced to dispense with the services of all officers in those departments whose salaries had not been voted, and that 700 had been dismissed; and what steps it was proposed to take to carry on these services. —Mr. RICHARDS replied: The facts are substantially as stated by the hon. and gallant Member. The precise number of officers who have been given notice, three months in every case, is 703. My noble friend, the Secretary of State, has the matter under consideration.

Experimental Inoculations of Animals.

Mr. PETHICK LAWRENCE asked the Minister of Agriculture whether the proposal to bring all experimental inoculations of animals with the living virus of certain highly dangerous diseases under the effective control of the Board of Agriculture, originally suggested in the Board's report for the year 1919, had been considered afresh: and whether anything had been done in the matter.—Mr. BUXTON replied: The proposal referred to has been considered from time to time, and it has come up for special consideration at the present moment in connexion with the investigation of foot-and-mouth disease. I am advised that experiments with the virus of this very contagious disease should be controlled, and measures will be adopted to give effect to this view.

Epizootic Abortion in Cattle.

Mr. BLACK asked the Minister of Agriculture whether he could give any figures showing the number of heifers and cows inoculated against epizootic abortion, and the results of such inoculations during the last three years.—Mr. BUXTON replied: Such information as it has been possible to collect with regard to these inoculations is not complete or sufficient upon which to base a general conclusion. I understand, however, that in a number of selected cases particulars are being collected and I hope that it will be possible to make these the subject of a report at a later date.

Guardians and Mental Hospitals.

Mr. ALFRED T. DAVIES asked the Minister of Health whether, by an Order in Council or other means, boards of guardians might have direct representation on the committees of management of the mental hospitals in the areas such guardians represent; and whether he would favourably consider the question at an early date.—Mr. WHEATLEY replied: The answer to the first part of the question is in the negative, and I doubt if an alteration of the law in the direction suggested is likely in the immediate future.

TUESDAY, APRIL 8TH.

Recruitment of Junior R.A.M.C. Officers.

Lieut.-Col. ASSHETON POWNALL asked the Secretary of State for War what action it was proposed to take to recruit junior officers for the Royal Army Medical Corps, in view of the present serious shortage.—Mr. S. WALSH replied: The matter is receiving consideration, but I am not yet in a position to make a statement regarding it.

ROYAL EASTBOURNE EYE HOSPITAL.—The annual report of this institution submitted to the annual meeting of the subscribers on March 28th notified that during the year 1923 the extension of the hospital premises had been completed, and the institution was now in such a state of efficiency as would enable it to compare favourably with other ophthalmic hospitals. The chairman paid a tribute to the work of the hon. surgeon, Mr. Geoffrey B. Lowe, to whose economical management, aided by the matron, the present sound condition of the finances was due. New cases during the year numbered 1177, as against 848 in 1922, despite the difficulties in accommodation and the absence of an operating theatre, disadvantages which had now disappeared with the inauguration of the new ward and operating theatre in the enlarged premises.

Medical News.

UNIVERSITY OF LONDON.—A course of lectures on Medical Hydrology, supplemented by demonstrations and clinical lectures at a British spa, has been arranged by the Board to promote the extension of University teaching in coöperation with the Committee for the Study of Medical Hydrology in Great Britain. The course will begin on May 6th, and end on May 9th, 1924. Dr. R. Fortescue Fox, Prof. M. S. Pembrey, Dr. S. Judd Lewis, Dr. David Brown, Dr. Charles W. Buckley, Dr. G. L. Kerr Pringle, and Dr. W. Bertram Watson will take part in the course, and a visit will be paid to Bath on May 8th, returning May 9th. All communications with reference to the course should be addressed to the hon. secretaries, Committee for Study of Hydrology, care of University Extension Department, at the University of London, South Kensington, S.W. 7, where the lectures will for the most part be delivered.

ROYAL SOCIETY.—The President and Council of the Royal Society have received from a donor who has desired to remain anonymous a gift of £10,000 for the prosecution of original research in medicine, with special attention to tropical diseases in British possessions, and to cancer and tuberculosis. They have also received from Messrs. Brunner, Mond, and Co. a gift of 500 guineas, to be used for the publication of the results of scientific research in chemistry, physics, and similar sciences.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a meeting of the President and Fellows of the Royal College of Physicians of Ireland held in the College Hall, Kildare-street, Dublin, on April 4th, Surgeon Vice-Admiral Joseph Chambers, M.D. Dub., C.B., C.M.G., hon. physician to H.M. the King, Director-General of the Medical Department of the Royal Navy, was admitted an Honorary Fellow of the College.

ROYAL MEDICAL BENEVOLENT FUND.—The annual meeting of the supporters of the Fund will be held at the rooms of the Medical Society of London, 11, Chandos-street, W. 1, at 5.30 P.M., on Tuesday next, April 15th, when the officers and committee for the ensuing year will be elected and the annual report and statement of accounts for 1923 received.

BENEKE CENTENARY.—On March 27th, the hundredth anniversary of the birth of Friedrich Wilhelm Beneke was celebrated at Bad Nauheim, where his memory is held in high esteem. Beneke was born at Celle in Hanover, became professor of medicine in the University of Marburg, and physician to the mineral springs of Nauheim, where he discovered the beneficial action of mineral baths on the heart and blood-vessels. For several years he was chief physician to the German Hospital in London, when he became closely acquainted with the organisation of hospitals and charitable institutions of the metropolis, knowledge which had its effect on his later work.

DR. SCHWEITZER'S RETURN TO AFRICA.—Dr. Albert Schweitzer, doctor of theology and doctor of music, as well as doctor of medicine, of Strasbourg, has just returned to Africa to take up again his work as a medical missionary. His sojourn in Europe during the war gave him the opportunity of lecturing and playing—he is a brilliant organist and interpreter of Bach—in this and most of the chief countries on the continent in aid of his African work, which he thus supports by his own efforts. Dr. Schweitzer paid a private visit to England last December when his suggestions that he should found, if possible, a second hospital on British territory—his original hospital is at Lambarene in the French Gaboons—were welcomed by the Colonial Office. He is now looking for a suitable site in the British Cameroons.

DONATIONS AND BEQUESTS.—By the will of the late Alderman Dr. Thomas William Thursfield, of Leamington Spa, the testator left £600 to the Warneford and South Warwickshire Hospital, Leamington, upon trust for investment and to apply the income in the improvement of the teaching of the nurses trained in that hospital, any balance being used for a medal or prize to the nurse passing the best examination, and £450 to the University of Aberdeen upon trust for investment and to apply the income for a Dr. Thursfield Gold Medal (or other award) for the best thesis for the degree of Doctor of Medicine.—Subject to certain contingent conditions the late Mr. E. Huntley of Branksome Dorset, who left estate of the value of about £35,000, bequeathed a large residue to be equally divided between the Royal Infirmary and the Eye Infirmary, Sunderland.

Sir H. M. Mallaby-Deeley has offered to double all contributions received for the Westminster Hospital from April 2nd to June 30th, up to a total of £16,000.

Dr. F. J. Willans, M.V.O., has been appointed Surgeon Apothecary to His Majesty's Household at Sandringham in the place of Sir Alan Reeve Manby, K.C.V.O., who has resigned.

Summer-time in Great Britain will take effect on the night of Saturday–Sunday, April 12th–13th, when clocks should be advanced one hour. In France, Belgium, and Holland summer-time took effect on the night of March 29th–30th.

King Edward VII. Hospital, Windsor.—The foundation-stone of Nurses' Hostel of the hospital was laid on April 5th by H.M. Queen Mary. The hostel is being erected as a war memorial, and in memory of Sir William Shipley, the late chairman of the hospital.

Cancer Hospital.—The annual dinner of the medical staff of this hospital was held at the Langham Hotel on April 2nd, with Mr. W. Ernest Miles presiding. Of the company present (about 80) more than half were guests. After the loyal toast had been honoured Mr. H. J. Waring, Vice-Chancellor of the University of London, gave the toast of the Hospital. He briefly outlined the history of its foundation in 1851 when cancer patients were not readily admitted to the general hospitals, and passed in review the recent advances made in the surgery of cancer. He discussed the ideal hospital buildings for such a purpose and concluded with a warning that in spite of all the research into the origin of cancer the only hope of cure still lay in surgery. In reply, the Chairman pointed to projected alterations in the buildings which would satisfy Mr. Waring's ideals. Though much effort and money was lavished on the electro-therapeutical department it was with the object of relieving suffering, for it was realised that at least up to the present no cures had been obtained. Sir Thomas Horder proposed the Health of the Guests, and Viscount Cave, Sir William Hale-White, and Captain Dyer, chief of the London Fire Brigade, replied. The final toast of a most successful dinner was that of the Chairman, proposed by Mr. Jocelyn Swan.

Royal West Sussex Hospital, Chichester.—Although the balance-sheet presented at the annual meeting of the governors on April 1st showed a small balance in hand, the financial position, it was explained, was a cause of some anxiety owing to the lack of definite annual subscribers. Since 1914 the annual subscriptions had been up to £1700, but they had now dropped to £1500. Despite the ever-increasing growth of the work, it was announced by the chairman that during the last four years expenditure had decreased by £3000. One very satisfactory feature of the year 1923 was the result of the Alexandra Day collection. In-patients during the year numbered 578, and out-patients 1761, who made 6713 attendances. In addition there were 1020 attendances in the X ray department, and 2509 attendances of patients for electrical massage. The great increase in the work of the X ray department had called attention to the lack of accommodation and a new arrangement was under consideration. It was also stated at the meeting that the governors were endeavouring to initiate a scheme in connexion with the training of nurses, so that nurses who went to the smaller hospitals could count two years' work there towards their certificate.

Royal Victoria Hospital, Belfast.—At the annual meeting of the hospital held on March 27th the report showed that during the year 1923 there were treated 4643 patients in the wards and 37,736 in the out-patient department. The average daily number of beds occupied was 325. The number of surgical operations performed was 2676, with a mortality of 3·44 per cent. The total number of deaths during the year was 276, which gives a mortality of 5·94 per cent. In the pathological department 1582 examinations were recorded. A follow-up department has been established to record the after-history of patients who have been treated or operated upon in the hospital. Every first and third Wednesday a laboratory meeting of the staff has been held, at which questions of clinical and pathological interest have been discussed. More than 60 diabetic patients have received treatment by insulin with very gratifying results, and in other specialised departments there was a considerable increase in the number of patients who received treatment. In the dental department, systematic orthodontic treatment for the correction of irregularities of children's teeth has been instituted. The number of students in attendance at th hospital was 319 in the winter session and 293 in the summer session. The income for the year under notice was £54,000, and the expenditure £55,000. The workpeople's contributions amounted to £19,000, an increase of over £1500 as compared with the previous year. The sum of £5100 was added to the capital account. The cost per bed was £135. During the year an extensive scheme of enlargement of the hospital has been undertaken to meet the ever-growing pressure upon its resources. Since the hospital was opened in the year 1903 the population of Belfast has increased by about 150,000, and the waiting list at the hospital never falls below 150, and sometimes exceeds 200. The building operations are now far advanced, and will afford 80 new beds, a new block for nurses, extensive additions to the extern department, and a new mortuary. New gynæcological and ophthalmic operating theatres, a common room for students, additional accommodation for the X ray department and the dental department are included in the plans. The total cost of the extensions will be about £80,000. An interesting feature of the year was the provision of the Princess Mary Cot, the funds for which were derived from the sum of money left over from the subscriptions raised by the women of Ulster to present Her Royal Highness with a wedding present. The cot was handed over to the hospital by the Duchess of Abercorn on Jan. 23rd, by whose instrumentality the sum of £250 for naming the cot was obtained. A signed photograph of Princess Mary overhangs the cot. The board records with much regret the decease of Sir John Walton Browne, D.L., one of its consulting surgeons. Professor T. Sinclair, C.B., F.R.C.S., has been appointed on the consulting staff, and has been succeeded on the visiting staff by Mr. S. T. Irwin. Mr. H. P. Malcolm has been appointed one of the assistant surgeons.

West Kent Hospital.—The annual meeting of this hospital was held recently at Maidstone. The report of the committee of management showed an increase in the number of patients in the various departments during 1923, but the present accommodation was not sufficient to meet the requirements of the neighbourhood and there was still a long waiting list of patients. The ordinary income had increased during the year by £1727, but it was still far short of the amount needed annually, and the year ended with an adverse balance of £1225. The committee expressed their special thanks to the members of the Pay Day Fund for their continued support, as the result of which £3437 had been raised. Dr. W. Shaw, who had been hon. physician to the hospital since 1904, having resigned his office, was appointed honorary consulting physician, and Dr. G. L. Atwater was elected hon. assistant physician.

Erratum.—In The Lancet of April 5th, p. 730, in announcing a meeting of the Royal Sanitary Institute, the second portion of the paragraph referred to a Congress at Bordeaux which is not that of the Royal Sanitary Institute, but of the Royal Institute of Public Health. Otherwise the information holds good.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, April 14th.

WAR: at 4.30 P.M.
Annual General Meeting:
Election of Officers and Council for 1924–25.
Paper:
Lieut. Colonel J. A. Anderson, R.A.M.C.: The Recent Trend of Military Hygiene.
The paper will be followed by a discussion.

Tuesday, April 15th.

GENERAL MEETING OF FELLOWS: at 5 P.M.
Ballot for election to the Fellowship.

Wednesday, April 16th.

HISTORY OF MEDICINE: at 5 P.M.
Paper:
Dr. Louis W. Sambon: Preventive Medicine among the Ancients (illustrated by slides, drawings, and ancient objects).

Easter Closing.

The Society's House and Library will be closed from Thursday, April 17th, to Tuesday, April 22nd, both days inclusive.

LONDON DERMATOLOGICAL SOCIETY.
Wednesday, April 16th.—4.30 P.M., A Clinical Meeting will be held at St. John's Hospital, when cases will be shown. After the meeting the Fellows' Dinner will be held at the Criterion Restaurant (price 5*s*.).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, April 14th.—10 A.M., Surgical Registrar: Surgical Pathology. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 P.M., Mr. Bishop Harman: Eye Department.

TUESDAY.—10 A.M., Mr. Steadman: Dental Department. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Department. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients.

THURSDAY.—11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Simmonds: Surgical Out-patients.

FRIDAY.—10.30 A.M., Dr. Scott Pinchin: Medical Wards. 12 noon, Mr. Endean: Venereal Diseases. 2 P.M., Dr. Burrell: Medical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily 10 A.M. to 6 P.M., Saturdays, 10 A.M., to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital.

(At 4.30 P.M.)

MONDAY, April 14th.—Dr. A. J. Whiting: Extra Systole.

TUESDAY.—Dr. J. Metcalfe: The Treatment of Skin Diseases by X Rays.

WEDNESDAY.—Mr. T. H. C. Benians: The Pathology of Blood Infections.

THURSDAY.—Mr. W. E. Tanner: Gall-stones.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY, April 15th.—4.15 P.M., Mr. P. R. Wrigley: Cervical Rib.

Appointments.

McDONALD, D. T., M.B., Ch.B. Edin., has been appointed Medical Officer of Health to the Belford Rural District Council.

M'GONIGLE, G. C. M., M.D. Durh., D.P.H., Medical Officer of Health for Stockton-on-Tees.

PRICE, H. P., L.R.C.P. Lond., M.R.C.S., Medical Officer to the Reading Post Office.

WHEATLEY, ELIZABETH, M.B., Ch.B. Glasg., an Assistant Medical Officer at the Belvedere Fever Hospital of Glasgow Corporation.

Certifying Surgeons under the Factory and Workshop Acts: **HALE**, R. E. V., M.B., B.Ch. Camb. (Harpenden): **MELDRUM**, W. J., M.B., Ch.B. Aberd. (Ibstock).

Vacancies.

For further information refer to the advertisement columns.

Aylesbury, Royal Buckinghamshire Hospital.—Hon. Radiologist.

Bethlem Hospital, Lambeth-road, S.E.—Two Res. H.P.'s. Each £25 per quarter.

Birmingham City.—Asst. M.O. £750. Also M.O. for Maternity and Child Welfare Work. £600.

Birmingham Union Dudley-road Hospital.—Obstet. and Gynæcological Resident. £500.

Bradford City.—Asst. School M.O. £600.

Bradford Royal Infirmary.—H.S. £150.

British Guiana Diamond Fields.—Government M.O. £500.

Cardiff, University College of, South Wales and Mon.—Prof. of Pathology and Bacteriology. £1500.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. £125.

Croydon County Borough.—Dental S. £600.

Eastern Dispensary, Leman-street, E.—Dent. Surg.

East London Hospital for Children, &c., Shadwell, E.—H.P. £125. Also Afternoon Cas. O. £120.

East Sussex County Mental Hospital, Hellingly.—Pathologist. £500.

Elizabeth Garrett Anderson Hospital, 144, *Euston-road.*—Asst. Radiologist. £100.

Hemel Hempstead, West Herts Hospital.—Res. M.O. £200.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—2 Asst. P.'s.

Huddersfield Royal Infirmary.—Res. H.S.'s. £200.

Infants Hospital, Vincent-square, Westminster.—Clin. Asst.

Kensington, Fulham and Chelsea Hospital, Richmond-road, Earl's Court, S.W.—Sen. and Jun. R.M.O.'s. £100 and £75 respectively.

Liverpool Eye and Ear Infirmary.—Hon. Asst. Aural S.

London Temperance Hospital, Hampstead-road, N.W.—Med. Registrar. 40 guineas.

Manchester Education Committee.—Asst. School. M.O. £600.

Manchester Royal Infirmary.—Res. M.O. £200. Also Asst. M.O. £100.

Northampton General Hospital.—Hon. P.

Nottingham Children's Hospital.—Res. H.P. £150.

Rainhill, County Mental Hospital.—Asst. M.O. £300.

R.A.M.C. Territorial Army.—Young Med. Practitioners.

Royal Chest Hospital, City-road, E.C.—Clin. Assts.

Staffordshire General Infirmary, Stafford.—H.P. £150.

Union of South Africa Government Mental Hospital Service.—Asst. P.'s. £460.

West Ham Union, Whipps Cross Hospital, Whipps Cross road, Leytonstone, E.—Fifth Asst. M.O. £434.

West London Hospital, Hammersmith-road, W.—Hon. Med. Reg.

Willesden General Hospital, Harlesden-road, N.W.—H.S. £100.

Willesden Municipal Hospital for Infectious Diseases, Brentfield-road, Neasden, N.W.—R.M.O. £373 9*s.* 3*d.*

Willesden Urban District Council.—Asst. M.O. £696.

The Secretary of State for the Home Department gives notice of vacancies for Ophthalmic Specialist Medical Referees under the Workmen's Compensation Act, at Ayr, Kilmarnock, Lanark, Paisley, Greenock, Renfrew, Bute, Isle of Arran, Stirling, Falkirk, Dumbarton, and Clackmannan. Applications should reach the Private Secretary, Scottish Office, Whitehall, S.W., not later than April 30th.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointment: Glastonbury, Somerset.

Births, Marriages, and Deaths.

BIRTHS.

HOSKIN.—On April 6th, the wife of T. Jenner Hoskin, M.D., Wimpole-street, W., of a daughter.

HURTER.—On April 1st, at Grassendale, Liverpool, the wife of Herbert R. Hurter, M.D., of a daughter.

LEWIS.—On March 31st, at Gordon House, Braintree, the wife of Dr. T. Percy Lewis, of a son.

MARRIAGES.

HAYES—HUDSON.—On March 7th, at the Cathedral, Bombay, Captain Sydney Nuttall Hayes, F.R.C.S., I.M.S., to Sybil Maud, only daughter of Dr. and Mrs. Wasdale Hudson, Parade, Cowes, I.W.

HINE—ROBERTSON.—On April 3rd, at Dundee, Montague Hine, M.D., F.R.C.S., to Jennette, younger daughter of Mr. and Mrs. J. Masson Robertson, of Alva, Clackmannanshire.

WALLACE—GRANT.—On April 3rd, at St. John's Presbyterian Church, South Shields, J. Montague Wallace, M.A. Camb., M.R.C.S., L.R.C.P. Lond., to Gladys, eldest daughter of Mr. and Mrs. J. Grant, of South Shields.

DEATHS.

BRAMWELL.—On March 31st, at Kenton, Devon, John William Bramwell, M.D., aged 72.

DYER.—On April 3rd, after an operation, Thomas Birch Dyer, M.D., of Brundall, Norwich, formerly Medical Superintendent, M.A.B. Asylum, Darenth, Kent, aged 78.

HAIG.—On April 6th, at Inverness-terrace, London, W., Alexander Haig, M.A., M.D. Oxf., F.R.C.P.

MACKAY.—On March 31st, at a nursing home, Edinburgh, John Sutherland Mackay, M.D.

RICHARDSON.—On April 1st, at Boscombe, after a short illness, Thomas Arthur Richardson, M.R.C.S., L.S.A., aged 69.

WALTER.—On April 2nd, at Stoke-under-Ham, Somerset, Richard Hensleigh Walter, M.B., C.M., F.S.A., aged 62.

WILLIAMS.—On April 1st, John Prichard Williams, M.R.C.S., L.R.C.P. Lond., Captain, R.A.M.C., of The Hermitage, Potters Bar, aged 30.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

A REPORT ON THE VOLUNTARY HOSPITALS SYSTEM.

The second report of the Somerset Voluntary Hospitals Committee [1] is noteworthy in that the voluntary hospital system and the attempts being made to preserve it are discussed on general lines, local conditions being used to illustrate the argument.

The record of the year for Somerset is regarded as the epitome of the hospital work and progress in the whole of Great Britain. The quality of the work done in the individual hospitals shows steady improvement. The increase in size, personnel, and equipment of several institutions is recorded, and it is noted that each year doctors and nurses do higher class work. The old tradition of service shows no sign whatever of weakening. The local hospitals have a very strong hold on the affections of the people.

Criticism of certain local conditions finds a place. The work of one of the special departments of the Royal United Hospital at Bath is said to overlap that of the Ear, Nose and Throat Hospital. Again, while the smaller hospitals were ordinarily only half full, and 150 beds or more were available daily for occupation, the Royal United, Bath, had throughout the year a long waiting list. In the Bath Infirmary there are 217 beds, of which 57 are ordinarily unoccupied. The distance which poor patients can afford to travel to obtain special treatment does not exceed about 20 miles, and access to specialists is practically withheld from about two-thirds of the county. Non-coördination means an uneven distribution of benefits, wasted potentialities, and an inefficient hospital service. The natural evolution towards a well-coördinated hospital system which the country is striving to work out, through its local hospitals and county and municipal institutions, is artificially hindered, in Somerset and throughout England, by the unwillingness of the cities to decentralise, and of the voluntary hospitals to coöperate with public bodies. In November, 1923, a conference of the representatives of all voluntary hospitals in Bristol, Somerset, and Wilts was held at Bristol, and it was resolved to constitute a joint hospitals committee for the three areas. This is the first step towards coördination. Many of the reports issued by hospitals are not complete. One was not issued until December. It is most desirable that the number of in-patients from each parish be disclosed, and how many are private patients. The committee ask that there should be a full medical report, such as will enable subscribers to ascertain the quality and extent of the work done.

The General Position Throughout the Country.

The report is, on the whole, pessimistic in tone. It is pointed out that the results of the energetic efforts made by hospitals, throughout the country, to redeem the financial position from the liabilities incurred during the period of the great war have been disappointing. It is against central general hospitals especially that deficits have piled up, and it is now apparent that they are due to something more than the temporary effects of the war. Most of these hospitals were founded during the eighteenth century, and for nearly 150 years did all the hospital work of the country. They were originally little more than hostels for the convenient treatment of the city paupers, and were maintained by quite a few wealthy men and women of the city; but they soon began to attract patients from the surrounding country. As manufacturers and merchants were, during the whole of the eighteenth and nineteenth centuries, becoming richer and richer, money was always forthcoming to meet capital requirements and the ever-increasing annual expenditure. Thus it became almost an article of faith with managing committees that extensions should keep pace with the demand, and that every effort should be made to increase this demand by conspicuously good work. By 1914, the teaching hospitals, and many other central general ones, had grown into enormous institutions, offering free treatment to all comers from everywhere, and to anyone who could not afford to pay the rapidly increasing cost of an operation in a private nursing home. Between 1914 and 1920 costs and salaries increased at an abnormal rate, but the margin of capital and income, available for charitable legacies and donations, did not expand in the same proportion; expansion was effectively checked by enhanced income-tax and estate duties, and the period of recurring annual deficits commenced.

The Traditional Assumptions of the Voluntary Hospital System.

The report contends that the English hospital system is based on certain traditional assumptions. It is assumed that the population is divided, by a sharp line of cleavage, into rich and poor, that those below the line are suitable beneficiaries of charity, able, perhaps, to pay something towards their maintenance when in hospital, but nothing for their medical and surgical treatment there, and those above the line are wealthy enough, and numerous enough, to support the hospitals, to pay the charges of nursing homes, and by high fees to remunerate the surgeons and physicians for all their hospital work. It is assumed, also, that the rich of the great cities can afford to provide hospitals, not only for their own poor but for an indefinite number of patients from outside, and further, that these outsiders spread the reputation of the members of the hospital staff and build up their private practices. And lastly, that there is no surgery, and no hospital worth the name, outside the boundaries of the great hospital centres.

The Present Position.

The committee express the belief that none of these assumptions are now justified by actual facts. The success of contributory schemes, and their enthusiastic acceptance, have revealed that a large proportion of hospital patients receive wages that should render them independent of charity, and that they desire to be independent. Whole classes of the "gentry" are kept by sentiment and tradition within the category of "rich," though barely able to meet the cost of living. The aggregate fees which those above the line are able to pay surgeons and physicians no longer constitute fair compensation for the services given to the population generally.

Within the last 30 years the greater part of England has been covered with a network of district and cottage hospitals, many of them admirably equipped, and staffed by visiting surgeons of acknowledged repute, or by men who have had special experience during the war, or by competent graduates who realise that the career of city consultants has become a hazardous speculation. These hospitals have arisen in response to reasonable and natural demands, by the people for treatment as near as possible to their own homes, and by the general practitioners for opportunity to do serious work. There can be no doubt that a large number of cases sent to central hospitals could be treated, at least adequately, in a local one. In the district and cottage hospitals many of the old traditions have been abandoned; outside patients are not admitted, and there is no arbitrary division of the population. It is being discovered that any average area can provide sufficiently good general hospital service for all classes, at a cost which no one finds ruinous, and that the necessary money can be raised by methods which all approve. The classes who provide the paying clientèle to consultants are finding that a district hospital offers a more complete equipment and better service than a city nursing home—at half the cost, and they are refusing to be shepherded into the cities at the tail of the poorer patients.

The Results of the Attempt to Preserve the Old Traditions.

That the very foundations of the voluntary hospital system have crumbled away has been recognised by the management of the central general hospitals, to the extent of soliciting payments towards the cost of maintenance, and regular contributions, from the patient class—but no further. The attempt to preserve the old traditions is reducing nearly all central hospitals to financial straits, and compelling them to resort to sensational, costly, and even undesirable devices for raising money; it is rendering the position of the consultants alarmingly insecure, and making it necessary for the junior staffs to ask for a living wage. It is causing grave discontent among the middle classes, who derive no benefit from the hospitals, and are called on to pay fees artificially enhanced by the antiquated rule which restricts their collection to a small percentage of the population.

To appreciate the general position it is necessary to understand how England is geographically divided for hospital purposes. The patients' register of any district or cottage hospital will disclose the parishes and villages from which its patients are drawn. A district hospital has ordinarily over 30 beds but less than 100; a cottage hospital 30 beds or under. Round any city there is ordinarily a clear space uncovered by any district or cottage hospital; the city itself and this clear space constitute the "city hospital area." Every central general hospital (which ordinarily has 100 beds or more) serves not only the city hospital area but admits patients regularly from an ascertainable number of cottage areas; the city hospital area, and these cottage areas constitute a "central hospital area." A central general hospital, to which a medical school is attached, admits patients from a large number of district and cottage areas, and overlaps less important central hospital areas; the whole region served might be termed a "teaching hospital area." It must be borne in mind that ordinarily from one-third to one-half of the in-patients in a provincial central general hospital come from outside the city hospital area, and that in teaching hospitals the proportion is very much larger.

---

[1] Bath: The Herald Press, North Gate. Price 6*d.*

The population of every city, district, and cottage hospital area readily admits its obligation to support its local hospital, so far as it benefits local residents. But appeals on behalf of any central hospital have little reaction as soon as the limits of a district or cottage hospital area are crossed, and, consequently, appeals within the city have to be frequent and vigorously importunate. If the experience of Somerset may be taken as having general application, there would be no difficulty in mapping out the whole country into these natural areas, and there are probably few exceptions to the general rule that every area is competent and willing to make hospital provision for its own population, provided that it be free to get the service it needs, and to pay for it in the way it finds most suitable.

From various tables set out in the report it is claimed that the following inferences can be fairly drawn:—

District and cottage hospital areas are not paying their fair share of the cost of the service from which they benefit.

Even the richest cities can no longer find the money for giving free, or very cheap, treatment to as many outside patients as they are attempting to.

It costs less to treat a patient in a district or cottage hospital than in a central general one, less in an ordinary general hospital than in a teaching one, less in a provincial teaching hospital than in a London one.

The difficulty which a central general hospital experiences in collecting from outside areas contributions proportionate to the cost of the services rendered to them varies with the distance of such areas. The wider the area served, the larger the hospital. Hence the probability that any central general hospital in the provinces will have a deficit increases with its size.

The minimum essential staff and equipment of a special hospital are greater than those of a general hospital, but the actual cost of treating each patient seems less. Hence, the cost per bed in a small special hospital is less, and that in a large special hospital is more, than that in a general hospital of corresponding size.

In London, and other cities containing several hospitals, there is in any year an indefinite, but not unlimited, amount which is forthcoming from the public for hospitals generally. For this the several hospitals compete. An important factor in determining the share secured by a particular hospital is the personality of the man who conducts its begging campaign. Though the standard of equipment and quality of service are ordinarily higher in the larger hospitals, the price of land, building costs, rents and wages are higher in crowded cities than in provincial towns or villages, and it is obvious that centralisation, so far as it draws to the city general hospitals cases that can be dealt with locally, involves heavy unnecessary expenditure. In the case of special hospitals centralisation leads to economy, though severely limiting the population which can obtain the benefits of special treatment. The smaller special hospitals are popular and well supported.

The Future.

It is contended in this report that if the English voluntary hospital system is ever to be placed on a permanently stable financial basis, and to provide for all classes a satisfactory and economical hospital service, if the consultants system is to be retained and a fair income assured to surgeons and physicians, certain essential conditions must be fulfilled. The cities must be relieved of some part of the excessive burden which they have shouldered, and be set free to give to the members of their own patient class something more than they now have—the precarious chance of admission if they are in immediate need of operation, or constitute "suitable material" for medical students. The cost of maintaining central general hospitals must be spread over the whole of their areas, and for this a contributory scheme of universal application should be devised, with its organisation based on natural hospital areas, which gives to every hospital such share as it actually earns, and to every contributor good value for his money, not seeking to exploit by purely sentimental appeal. Suitable accommodation must be provided for the middle classes, and they should be given opportunity to insure against serious illness and the normal cost of surgical and special treatment. The claims of the junior staffs to reasonable payment must be admitted, and be taken into consideration when estimating the normal cost of a patient for purposes of the contributory scheme. District and cottage hospitals must be encouraged to do the fullest work of which they are capable. Facilities for special treatment must be extended to country populations remote from the great centres, and the grievance of the country "panel doctor," that he gets no remuneration for hospital cases, be remedied. The voluntary hospitals must work with county and municipal institutions. The cities must abandon their position of isolation, and actively recognise that between them and the country areas exist close ties of mutual obligation. There must be real coördination.

THE FOUNDING OF THE U.S.A. WAR HOSPITALS.

A VALUABLE work [1] has appeared in handsome guise, telling how hospitals for the new armies of the United States were found, built, administered, and afterwards closed. An abstract should be published, for these essays by many hands are so detailed that few will have time to find in them the special points they may be seeking; hardly will even military medical experts be able to assimilate all that is set out. In 1917 there were 9530 beds in military hospitals of all kinds in the United States. At the Armistice there were 120,916 equipped and 27,000 nearly ready, a wonderful tribute to the sound organisation and power of expansion of the U.S. Army Medical Department. The type of hospital favoured was the pavilion, first (p. 16) seen in the R.N. Hospital at Plymouth (1750), and reproduced, after the experiences of the Crimean War, in the Herbert Hospital at Woolwich.

When the United States entered the war, hospitals for the Expeditionary Force were planned to take 2 per cent. medical and 5 per cent. surgical casualties, of whom four out of five were expected to be walking cases. The number of beds in wards varied from 14 to 100; smaller wards were provided for raw troops unaccustomed to live together, larger for trained soldiers, become relatively immune to infectious diseases. Each patient had 800 cub. ft. of space in a ward 11½ ft. high, and some 25 ft. wide, with 70 to 85 sq. ft. of floor area to each bed, and 3 ft. or 3½ ft. between beds. The windows were between alternate beds (two beds between each pair of windows), so each bed had half a window and its own share of light and fresh air; the window surface was one-tenth of the floor area, and ventilation was by sliding sashes and louvred (baffled later to keep out snow) ridge ventilators. Artificial ventilation of a six-story hospital is mentioned on p. 442, but most hospitals were single-storied. The wards were at right angles to the connecting corridors, "annexes" at the nearer, a "solarium" or sun-bath at the further end. Round the ward ran a verandah on to which beds could be wheeled. In the annexe there was, next the ward, a bed-pan room one side, on the other, at first, the nurse's room; later she was given her desk in the ward itself for her papers. There was a serving kitchen (very little cooking was done here); a slop sink and closet for brooms, cleaning pails, &c.; an office for the medical officer; a treatment room; several "quiet" rooms for serious cases (10 per cent.); for every 15 or 20 patients a w.c. seat (no partitions); at first washing-basins in the same proportions (later the basins were withdrawn, and taps remained over a trough); shower baths were 1 for 25, and, like the ablution taps, were supplied with tepid water from a tank with an automatic heat regulator, but one fixed bath with hot and cold taps was also fitted; one urinal stance for every 25 beds. There was always a hospital laboratory, but a clinical laboratory was provided for each 200 beds.

The main hospital kitchen probably served not only the patients but the hospital staff as well. It was planned so that orderlies had not to enter it, thus the cooks were not obstructed. On one side of the kitchen was the hospital store, on the other a corridor, with the main dining-room just across it, thus the food would be served as hot as possible. In the kitchen food was put into large containers, 15 in. by 12 in. by 11 in. deep, and four held dinner for 160 men; in the first soup, in the second potatoes, meat and gravy in the partitioned third, with a second vegetable (two-thirds), and the pudding (one-third of the space) in the fourth. The containers fitted on to the food wagons, and carried meals to the dining-room or to the wards. When staffs dwindled, food was distributed in the dining-room on a "cafeteria" system (for which the editors have only praise), introduced into the restaurants of the United States by Italians. Each patron on arrival takes his place in a queue, and as it passes forward he lifts a tray from a shelf, on it puts what crockery he needs, and at the counter the servers give him his helpings of food, all which he takes away with him to his table. Thus he is his own waiter, and staff is economised. After his meal he returns his used mess-gear to another counter near the kitchen, where are the dish-washing machines. It is found that 20 men can serve themselves from one counter (30 to 35 ft.) per minute, 10 to 15 minutes suffice for each man's meal, thus 300 men are served per hour per counter. Detailed plans are given with exact measurements, even of the food-wagons, the fish-boxes, and the lavatories of the cooks (who are all free from typhoid).

---

[1] The Medical Department of the U.S. Army in the World War. Vol. V.: Military Hospitals in the United States. Washington: Government Printing Office. Pp. 857. $2.25 (9s.).

There are full accounts of the auxiliary services of the hospitals, the canteens, hospital magazines, housing of the staff, recreation provision for patients and staff, training courses for medical officers (even telling how the less valuable were eliminated). The influenza epidemic of 1918 severely tested the organisation of hospital and the zeal of their staffs. Camp Grant Hospital had 642 patients on Sept. 21st, 1918, and had suddenly to receive 194 fresh cases of influenza that day. By that day week there were 3346 patients in hospital, and 798 were admitted. Deaths had so far been few, but they now increased, and new cases fell off, so on Oct. 6th there were only 370 admissions, with 430 discharges, but there were 99 deaths. The story of this outbreak (pp. 241 seq.) will well repay perusal. A laundry of its own usually saved money to a hospital, especially if it did gauze reclamation. Gauze, taken off a patient, was put for 12 hours in 1 per cent. cresol solution, boiled, washed in a machine, bleached, and dried. It was then put up in suitable parcels, sterilised, and used again without any disadvantage.[2] Hospital laundries always pressed patients' uniforms. A small motor truck with trailer, both quite small, were found most useful for taking stores issued round the hospital that was lucky enough to have "found" them. Stores and equipment of wards are, technically, "property," and it was found necessary to have a "property officer" in each section to watch over it: the chief officer of the section had no time for even that important work, and it fell to a specially designated junior officer. Fire protection was most carefully watched in these so often wooden hospitals; thus, kitchens were built with expanded-metal, instead of wooden, laths.

The index and illustrations of this book are, like the paper and printing, very good. The regimental inspection room (p. 108) plans are just what a medical officer wants and hopes for. Alas, that it should be so often in vain.

HANDBOOKS ON BRITISH AND FOREIGN SPAS.

THE British Spa Federation, comprising the spas of Bath, Buxton, Cheltenham, Droitwich, Harrogate, Leamington, Llandrindod Wells, Strathpeffer, Woodhall, and New Zealand, have issued their new Federation Handbook,[3] which is intended for the use of members of the medical and allied professions. A copy of it is being sent to every medical man in the country. The outlines of medical hydrology and spa treatment as practised in this country are dealt with clearly and concisely. The general practitioner will find it of much help in advising his patients as to the choice of a spa. The book is illustrated, and contains an introduction by Dr. Fortescue Fox.

The object of another small guide[4] on a cognate subject which has reached us is to aid in the choice of a spa or health resort for patients suffering from illness as a result of residence in the French Colonies. It deals not only with the well-known spas in France, but also with those in the French Colonies. Information, from trustworthy authorities, in a simple and handy form is laid before the practitioner. The book is illustrated and contains a preface by Dr. Paul Carnot, Professor of Therapeutics, Paris.

RESEARCH ON CONTRACEPTIVES.

TWO years ago a special medical research committee was constituted by the Society for Constructive Birth Control and Racial Progress, with the allotted task to consider critically the physiological and psychological reactions of various methods of birth control. The members of this committee are as follows: Sir James Barr, Sir William Bayliss, Mr. Harold Chapple, F.R.C.S., Dr. Jane Hawthorne, Dr. George Jones, Barrister-at-law, Dr. Maude Kerslake, Sir W. Arbuthnot Lane, Sir John MacAlister, Sir Archdall Reid, Dr. Christopher Rolleston, Dr. D. Sommerville, Mrs. Marie Stopes, D.Sc., Dr. H. M. Telling, Dr. Mather Thomson, and Mr. E. B. Turner, F.R.C.S. The proceedings and minutes of this committee are confidential, and none of its deliberations is published, except about points which are specially passed for publication. A number of new or supposedly new methods have been brought before it from various quarters, and a statement just issued states that due consideration confirms the view that no one method is applicable, but that several of the simple and well-known methods which have had a long trial still are the best to meet ordinary requirements. At the last committee meeting the following resolution was passed for publication: "The Medical Research Committee of the Society for Constructive Birth Control and Racial Progress wishes to place on record its joint and several opinion that the methods now used at the Mothers Clinic are the best known at the present time." Communications from anyone desiring to bring matters for discussion before the research committee, or to present scientific results for its consideration, should be addressed to the hon. secretary, C.B.C., 7, John-street, Adelphi, London, W.C. 2.

Corrigendum.—Mr. J. B. S. Haldane writes from the Biochemical Laboratory, Cambridge, to correct an equation which appeared in his article on Human Tissue Alkalinity (THE LANCET, March 15th, p. 537). This should run:—

$$2\,NH_4Cl + 2\,NaHCO_3 = 2\,NaCl + CON_2H_4 + CO_2 + 3\,H_2O.$$

THE presidential address on Environment and Health delivered by Mr. Charles P. Childe at the ninety-first annual meeting of the British Medical Association, held at Portsmouth in July, 1923, has been reprinted as Fabian Tract No. 208, and may be obtained at the Fabian Bookshop, 25, Tothill-street, Westminster, S.W. 1, price 2*d*.

CATALOGUE NO. 234 (1924) of scientific books issued by W. Heffer and Sons, Limited (4, Petty Cury, Cambridge), contains special sections dealing with (8) Physiology, Anatomy, and Medicine; and (9) Psychology and Psycho-Analysis. In the former is included an important collection of journals on ophthalmology and otology, and many other series or partial series of archives, journals, and centralblatts are offered for sale.

Messrs. Burroughs, Wellcome and Co. inform us that the medical supplies carried by Squadron-Leader Maclaren, who is in command of the British machine engaged in the round-the-world flight, consist of two light aluminium cases containing emergency bandages, dressings, sundry surgical appliances, as well as "tabloid" medicines in featherweight containers representing 364 separate doses. The complete medical equipment weighs only 24 ounces. The American expedition, organised by the U.S.A. Army Air Service, which started eight days before the British, has each of its four airplanes similarly equipped with an aluminium case containing "tabloid" medicaments and dressings.

The Services.

ROYAL ARMY MEDICAL CORPS.

Capt. F. H. Woods retires, receiving a gratuity.

ARMY DENTAL CORPS.

Capt. E. Smith retires, receiving a gratuity.

TERRITORIAL ARMY.

Lt.-Col. M. B. Ray, from R.A.M.C., T.A., to be Col. and Asst. Director of Medical Services 47th (2nd Lond.) Div. T.A.

Capt. E. G. Howell resigns his commn. and retains the rank of Capt.

E. A. Wilson to be Lt.

Capt. J. H. P. Fraser, from Gen. List, to be Maj. and to command 7th (Southern) Sanitary Coy.

ROYAL AIR FORCE.

Flight Lt. E. G. S. Hall resigns his short service commission.

Flight Lt. (Hon. Squadron Leader) A. E. F. F. Huntsman relinquishes his temporary commission on account of ill-health, and is granted the rank of Squadron Leader.

Flight Lieut. V. R. Smith is granted a permanent commission in the rank stated.

Flight Lieut. (Hon. Squadron Leader) G. D. Kerr relinquishes his temporary commission on ceasing to be employed and is permitted to retain the rank of Flight Lieut.

Flying Officer J. M. Rourke relinquishes his short service commission on account of ill-health.

INDIAN MEDICAL SERVICE.

Lt.-Col. T. H. Symons to be Maj.-Gen.

Capts. P. J. Veale, Heerajee Jehangir Manockjee Cursetjee, P. F. Gow, J. S. S. Martin, J. W. Jones, and J. H. Hislop to be Majs.

Lt. P. A. C. Davenport to be Capt.

Temp. Capt. P. A. C. Davenport to be Lt. and to retain his temp. rank of Capt.

J. F. Shepherd to be Lt.

The King has approved the grant of a temporary commission to Khushi Ram as Lt.

---

Lumleian Lectures

ON THE CLINICAL FEATURES OF
FOREIGN BODIES IN THE BRONCHI.

Delivered before the Royal College of Physicians of London

By THOMAS McCRAE, M.D., F.R.C.P. Lond.,
PROFESSOR OF MEDICINE, THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

(*With Illustrative Plate.*)

LECTURE II.

Delivered on April 8th, 1924.

Interpretation of Physical Signs.

The interpretation of the physical signs due to a foreign body in a bronchus will not prove easy for one who solves the problems of physical diagnosis by rule of thumb, who has one formula of signs by which he diagnoses pneumonia and another by which he diagnoses pleurisy. In some cases the findings are easy to interpret, but often there are puzzling signs which require care for proper valuation. This is especially true in children in whom there are more variations, especially in the signs obtained on percussion, than in adults. Certain points may be mentioned. In children, especially if the symptoms are acute, it is wise to go to work slowly and utilise inspection as fully as possible. This gives such important information that it should always be thorough. A child held in the nurse's arms will often become quiet and permit a satisfactory examination of the back. Percussion is not always satisfactory if done while a child is crying, as it then often gives confusing results. Auscultation, on the contrary, may give valuable results if done while the child is crying. If the signs are puzzling, repeated examinations should be made. The remarkable variation, even from hour to hour, especially in the signs obtained by percussion and auscultation, deserves special emphasis. In the study of the signs it is important to consider what may occur in the air passages and what results may follow the presence of the foreign body. A realisation of these points aids greatly in the interpretation of the signs. They may be noted as follows :—

1. *The Foreign Body Itself.*—A safety-pin gives but few changes and may not obstruct the passage of air sufficiently to cause any local signs in the lungs supplied by the bronchus in which it lies. A small metallic body may set up slight local irritation but interfere little with the passage of air. A round body such as a seed or nut may completely obstruct a bronchus at once and shut off the portion of lung supplied. In other cases the obstruction may not be complete at first, but soon becomes so by the resulting swelling of the mucous membrane. The blocking may be intermittent and give changing signs.

2. *Irritation and Inflammation.*—These vary greatly, dependent to a large extent on the character of the foreign body. A peanut sets up an intense inflammatory process which causes signs of itself and by swelling of the mucous membrane may completely close the bronchus. The inflammation may extend to other bronchi than the one affected. In cases of some duration the formation of granulations may extend for some distance.

3. *The Presence of Secretions.*—These may cause signs in the lung supplied by the affected bronchus. If air and secretions are both present many signs—especially on auscultation—are produced. If secretions accumulate and the air-supply is cut off, the air present is absorbed and the signs of a collapsed or "waterlogged" lung result. Secretions may pass into other portions of the affected lung or to the bronchi of the opposite side and cause signs there.

4. *Shifting of the Foreign Body.*—This is not infrequent and may be responsible for signs in two lobes or in both lungs. The picture at first is confusing and the greatest safeguard is in studying the signs carefully for a short period. The area first affected usually clears rapidly after the foreign body has shifted.

Anatomically it may aid to remember that there are several classes of cases : (1) Those in which a bronchus is completely plugged by the foreign body or by it plus swelling of the mucous membrane. In this case the signs should be easy of interpretation as the supplied lung is without air, collapses to a greater or less extent, and usually soon contains considerable fluid and secretion. (2) Those in which the bronchus is partially occluded and in which air and secretions are both present—perhaps in varying amounts at different times. (3) Those in which the foreign body acts as a ball-valve and in which the amount of air in the affected lung is greater than normal. The condition should be readily recognised by careful examination, especially by inspection.

Methods of Examination.

Inspection.—This cannot be too thorough and in restless children time and patience may be necessary. Inspection of the back should not be forgotten. It may be stated as a rule—from which it is doubtful if there are any exceptions—that there is always decreased expansion on the affected side. If the foreign body has shifted from one side to the other or portions of a foreign body (such as a nut) are present on both sides, then the change in expansion will be bilateral. The affected side may show some decrease in size, most evident if a lower lobe is affected, the bronchus is completely occluded, and collapse has occurred. If the foreign body has a ball-valve action the affected side is often larger but shows decreased expansion. The evidence of the extent of movement of the diaphragm should be carefully studied. It is less on the affected side, more especially if a lower lobe is involved. Evidence of displacement of the heart may be evident.

In some cases the only observable change is *decreased expansion.* This is seen particularly when the foreign body is metallic, such as a pin. It occurs when there is no evidence of obstruction to the passage of air or of changes in the bronchi or lung beyond the foreign body. The explanation of this phenomenon is difficult to give, but it probably represents a sensory reflex. The foreign body irritates a sensory ending in the bronchial mucosa which may result in a reflex contraction of the bronchial muscles. W. S. Miller[1] has shown that the action of the bronchial muscles in expiration is active rather than passive. The work of O. Larsell shows a mechanism which allows of expansion and contraction of the bronchi longitudinally during inspiration and expiration. Interference with the normal action of the bronchial musculature may be thus explained.

Palpation.—The transmission of the voice vibrations will vary with the degree to which the bronchus is occluded. If this is complete the vibrations are absent or present to a very slight extent. Accurate observation in children is often difficult. The voice may not be strong enough to set up vibrations of any force, in which case advantage should be taken of crying. In some cases in which there is "drowned lung" there may be some transmission of the vibrations, but this is usually slight. With a partially plugged bronchus the vibrations vary from time to time, but are likely to be somewhat decreased.

Percussion.—If the possible anatomical changes are kept in mind there should not be much difficulty in interpreting the findings. As many of the cases occur in children, it should be remembered that in them tympany is a common finding with various pathological conditions. If the foreign body allows air to enter, but not to leave an area of lung the note will be hyper-resonant or tympanitic. On comparison with the opposite side, the normal lung may seem to yield an impaired note. Careful inspection and percussing first on the normal side should prevent this error. If the bronchus is completely plugged, as soon as the contained air is absorbed, the note shows dullness to flatness. Shortly after the bronchus is occluded, there may be collapse of the lung giving a quality of tympany associated with dullness. Later, as secretions accumulate, the note becomes flat. In case of partial obstruction or obstruction which varies in degree from time to time, there will be varying combinations of dullness, normal resonance, and tympany. The reason for the alterations is evident, as the quantity of contained air, the amount of retained secretion, and the extent of collapse of the lung vary from time to time. In case of doubt in such cases a study of the signs at intervals usually clears up any difficulty. Marked changes are sometimes seen in a few hours if there is considerable secretion which accumulates for a time and then escapes, allowing some air to enter. The signs may be somewhat the same as may be found in cases of abscess, which is often present in cases of some duration.

---

[1] Amer. Rev. Tuberculosis, 1921, v., 689.

There are some findings which deserve mention. In children in whom the lower lobe bronchus is completely blocked there may be flatness in the axilla and adjoining back to about the scapular line, but between the latter and the spine there is dullness with a varying degree of tympany. This may occur in cases of long duration, so that it cannot always be due to some air being retained. Is it possible that in these cases there is some shifting over of the opposite lung and that the note is transmitted from it? In these cases distant blowing breathing is sometimes heard over the same area. Another change is apparently due to collapse of the lower right lobe. If this occurs suddenly, with marked displacement of the heart to the right, the middle lobe is shifted to the right and resonance is found over an area usually occupied by the lower lobe.

The sense of *resistance* does not aid greatly except in cases of flatness over a lower lobe when a diagnosis of effusion—serous or purulent—might be made. The resistance over a "drowned lung," or one containing much secretion, is not as marked as over pleural fluid. In an occasional case in which there is a great accumulation of fluid and secretion below a body which completely plugs the bronchus, the sense of resistance may be marked and even suggest pleural effusion. In such a case it is the resistance of fluid in the lung which we are feeling. Extreme difficulty, however, is rare.

Auscultation.—The study of the breath sounds is often very helpful and sometimes most confusing. If one lung is shut off, the respiration will be more marked on the other side and the breath sounds over the sound lung exaggerated and harsher, but not altered in their essential quality. Over the lung supplied by an occluded bronchus the breath sounds are absent or very much decreased. In such cases it is not uncommon in children to hear very distant breath sounds which may have a slight blowing quality, but they do not have the character of pneumonic breath sounds. This is neither invariable in cases with the same variety of foreign body nor constant in the same patient. If the bronchus is partially plugged the breath sounds are harsh and may have a blowing quality with prolonged expiration. The loudness and roughness are dependent on the extent of the narrowing due to the foreign body and to the presence of secretions. In these partially occluded cases the breath sounds often vary from hour to hour. The voice sounds are fairly parallel to the breath sounds.

Râles.—Their number and character depend on the amount of secretion and the changes in the mucous membrane, and hence there are many possibilities for variation. The secretions may, and often do, enter into other bronchi than the one involved, and not infrequently the resulting râles are louder and more numerous over other portions of the lungs than the one supplied by the affected bronchus. This is especially marked in the peanut cases in which there is a general tracheo-bronchitis. The râles are loud and coarse, and occur with respiration and expiration. Râles are often heard over the upper lobe of the lung when the foreign body is in the lower lobe bronchus. They vary in character, but are usually medium or coarse. If there is partial occlusion with some air and secretion below the foreign body, many râles are usually heard, some of which may be bubbling. Over the area supplied by a completely plugged bronchus there are no râles as a rule. In some cases râles are particularly loud over the area where the foreign body is situated.

In a few cases of a small metallic foreign body peculiar râles, very fine in character, have been heard over a limited area corresponding to the situation of the foreign body. These occur usually at the end of inspiration and suggest the crackling of very fine soft tissue paper. They are not loud, but have a characteristic fine quality.

With a foreign body in the trachea there may be very loud râles of many kinds heard throughout both sides of the chest. In narrowing of the larynx from œdema there may be similar findings with rough breath sounds, the cause of which is evident.

SIGNS PRODUCED BY VARIOUS KINDS OF FOREIGN BODY.

Pins.

The aspiration of pins, either the ordinary or safety variety, is comparatively common and will continue as long as the mouth is used as a holder for them. With a pin held in the lips, the person may be startled, cough, or begin to laugh, any of which may result in the pin being aspirated.

Safety-pin in Bronchus.—A woman, aged 32 years, two weeks previously coughed while holding a safety-pin in the mouth and aspirated it. She had a severe attack of coughing immediately and after this she had a tickling sensation and an occasional hacking cough. On examination she was comfortable without dyspnœa or cough. The only physical sign was diminished expansion on the left side. There was no change on percussion and the breath sounds were everywhere clear and the same on the two sides. The X ray study showed the pin (Fig. 1) in the left main bronchus without any evidence of change in the lung beyond the pin. Three hours after the removal of the pin by Dr. Jackson the expansion was found to be equal on the two sides.

A child, aged 10 months, was brought with the history that a week before the parents heard her choking and found her with severe dyspnœa. A small safety-pin which had been fastened in her clothing was missing. An X ray examination showed the safety-pin in a bronchus and two unsuccessful attempts at removal were made elsewhere. On examination the child seemed perfectly well and there was no dyspnœa or cyanosis. On inspection there was markedly decreased expansion of the right side, most marked below. Percussion was normal throughout and no difference could be found. The breath sounds were perhaps slightly rougher in the lower right axilla, but the difference was very slight. Not a single râle was heard. On bronchoscopy there was considerable subglottic swelling (probably due to the previous bronchoscopies) and the pin was found deep in the right lower lobe bronchus.

From the physical signs alone it is not possible in the majority of cases to make a diagnosis of the presence of an ordinary pin in a bronchus or to decide as to its location. With a definite history of aspiration only the affected side can be determined. Without a history of aspiration no suspicion may be aroused, although decreased expansion without any other sign should suggest the possibility. An X ray study gives the diagnosis without difficulty. The time required for the return of normal expansion after the removal of a pin is variable. In one patient the expansion was equal on the two sides within three hours after removal. In other cases a week has elapsed before normal movement was restored. In general it seems that the lower in the bronchus the pin travels, the longer the time required for restoration of the normal expansion.

If the pin has a relatively large head the signs are more marked and more accurate localisation is possible, as is illustrated in the next two cases. In the second one a remarkable shifting of a long pin is shown.

Hat-pin in Left Bronchus.—A child, aged 10 years, was admitted on Feb. 11th, 1922, complaining of slight cough and dyspnœa. On Dec. 30th, 1921, the child took a pin from her clothing and put it in her mouth. Another child slapped her on the back and in throwing her head backward she aspirated the pin. She states that it went down without any disturbance. An attempt at removal was made elsewhere the same night and two subsequent ones later: all were unsuccessful. The symptoms, even with the repeated bronchoscopies, have been very slight. The patient showed no distress, dyspnœa, or wheeze. Expansion was diminished in the lower left chest. When first examined there was slight relative dullness in the lower left back, which came to about the mid-axillary line. After vigorous breathing this was distinctly less marked. On auscultation very little change was made out, but when the dullness was present at the lower left back the breath sounds were quieter over this area. In the fifth and sixth interspaces, about an inch outside the left nipple line, a moderate number of very fine crackling râles were heard, and over the area of dullness medium crackling râles were heard, mostly with inspiration. The signs suggested that the pin was low down in one of the branches of the lower left lobe bronchus and had a larger head than the ordinary pin. The pin was found in the posterior vertical branch of a posterior subdivision of the left lower lobe. Shortly after removal there was still diminished expansion in the lower left and a few râles were heard. Two days later the difference in expansion was very slight. The X ray study showed practically no change in the lung tissue.

Shawl-pin in Bronchus.—A girl, aged 18 years, came with the history that two days before she had been picking her teeth with a shawl-pin, about two inches long, when it suddenly "went down." She states that it went down easily and she had no coughing or gagging. She is positive that she has not had any symptoms whatever. On examination she had no distress or dyspnœa. There was much less expansion on the right side with slight dullness on percussion over the middle and lower lobes and the breath sounds less well heard over the same area. Not a râle was heard. In the next two days the breath sounds over the lower lobe were less marked. The X ray study showed the pin in the *right* main bronchus, the point being just at the bifurcation of the trachea and the head below the upper lobe bronchus. Before the bronchoscopy was done a fluoroscopic examination was made and the pin was seen to have shifted to the *left* main bronchus. At bronchoscopy (Jackson) the right main bronchus showed the mucosa reddened but without any appreciable swelling. The pin was removed from the left main bronchus. Three days later the expansion was equal, there was slight dullness over the lower right lobe, but the breath sounds were practically normal.

Portions of wire are not common and the following case is of interest:—

Wire in Bronchus.—A child, aged 11 years, came complaining of cough, fever, and dyspnœa on exertion. Two years before she "choked" on a piece of wire shaped like a fish-hook and soon after was in bed for two weeks with a "cold." Slight dyspnœa followed and has existed to the present. A few weeks before admission she ran in a race and became very dyspnœic. On examination the child was well developed and did not have any clubbing of the fingers. There was no wheezing respiration. Expansion was markedly less on the left side. The percussion note did not show any definite change over the fronts, but there was marked dullness over the lower left axilla and back. The breath sounds were somewhat less well heard over the upper left front than over the same area on the right side. In the left axilla and over the lower left back they were very distant. Over a small area near the angle of the scapula they were tubular but heard distantly. On different examinations the breath sounds were found to vary greatly in loudness. Râles were heard on some occasions, but at other times not a single one was noted. The signs suggested that the obstruction was probably due largely to swelling of the mucous membrane and granulations. At bronchoscopy (Jackson) a large mass of granulation tissue was found projecting from the left bronchus and bloody pus came from below. The foreign body was found embedded in the swollen mucosa. After its removal no change was found in the signs except an increased number of râles. Two days later the breath sounds were better heard, but there was little change in expansion or on percussion. Six days later the expansion was decidedly better and the dullness was less. The breath sounds were still distant on quiet breathing, but were well heard on deep breathing.

Tacks, Nails, and Screws.

These gain entrance to the air passages comparatively frequently and usually give a fairly clear-cut picture. The head of a tack enters the bronchus first and passes down until it can travel no farther. The blocking of the bronchus is usually complete, or nearly so, by the object itself, and if any opening remains the resulting swelling of the mucous membrane soon closes it. The signs are those of complete blocking of the bronchus. In a recent case a thumb tack was so placed that the diameter of the head was parallel to the long axis of the bronchus. The only sign was decreased expansion, but as it had only been in the bronchus for one day, very little irritation had been set up. A nail may not block the bronchus itself, and air may pass it, for some time at any rate. Illustrative cases are as follows (see Figs. 2, 3, and 4):—

Tack in Bronchus.—A child, aged 3½ years, was admitted on Oct. 30th, 1923, with cough and fever. Two days before, while lying on his back on the floor, he had a sudden choking attack and became very blue. The mother did not know of his having anything in the mouth, but later the child said that he had swallowed a tack. Examination showed markedly diminished expansion on the right side, with dullness over the middle and lower lobes. The breath sounds were somewhat decreased over the upper right lobe and very distant over the middle and lower lobes. A few coarse râles were heard. The X ray showed considerable secretion in the middle lobe and less in the lower lobe. The tack was found in the right bronchus. Immediately after removal the dullness was unchanged, but harsh breath sounds were heard everywhere without any râles.

In many of the tack cases the foreign body had been present for a considerable time, and in this event the changes are fairly uniform. There is a rapid formation of pus which may be retained or small amounts may escape occasionally. Changes result in the lung and bronchi, such as abscess, cavity formation, and bronchiectasis. Some degree of fibrosis is common. An illustrative case is the following:—

Tack in Bronchus.—A girl, aged 14 years, was admitted on Jan. 6th, 1923, complaining of cough and fever. In October, 1920, the child had a tack in her mouth. While laughing the tack disappeared, and this was followed by a severe attack of coughing and choking. The child did not tell anyone about this. In December, 1920, the patient had an illness which was diagnosed as broncho-pneumonia, and a second such attack in March, 1921. Since this last attack the cough has been constant. This was dry for a time, but in November, 1922, sputum began to be brought up, a suspicion of lung abscess was aroused, and an X ray examination made, which showed a tack in the right lung. An unsuccessful bronchoscopy was done elsewhere, and a very severe reaction followed this. On examination there was marked limitation of expansion on the right side, especially below, with dullness from about the third rib. Over this area the breath sounds were rather distant and of blowing quality, with many râles of various kinds. The vocal fremitus and voice sounds were distinctly increased. About the angle of the scapula there was an area of whispering pectoriloquy. The breath had a very foul odour. There was no wheeze. A great many râles were heard over the area of dullness and the signs suggested either abscess or bronchiectasis below the foreign body. The X ray study showed the tack in the posterior branch of the furthermost bronchus, head downward, with very marked changes in the lower right and middle lobe. At bronchoscopy (Jackson) the bronchus was found to be narrowed below the middle lobe, and below this it had widened into a cavity deep down in which there was a mass of granulation tissue in which the tack was buried. Within a couple of days there was distinctly more expansion on the right side.

Teeth and Dental Material.

The aspiration of teeth, or portions of teeth, usually occurs when extraction is done under anæsthesia. These cases are not uncommon and their comparative frequency suggests the need of the greatest care by dentists. In some of the cases the dentist was positive that every extracted tooth was safely accounted for, but one was found in a bronchus just the same. Portions of dental material may become loose and be aspirated. In a few cases a small piece of apparatus slipped down while the dentist was at work.

Tooth in Bronchus.—A woman, aged 29 years, was admitted on March 19th, 1923, complaining of cough, much wheezing, and pain in the right chest. On Jan. 5th, 1923, she had some teeth extracted under gas anæsthesia. Immediately after she had a sensation of something having lodged in her throat and wheezing was noted soon after. Cough followed with foul-tasting sputum. A week after the extraction she brought up blood-tinged sputum. The patient showed marked decreased expansion on the right side, especially below. The note over the left lung and upper right lobe was clear; over the middle and lower right lobes there was marked dullness. The breath sounds were well heard over the upper right lobe accompanied by many musical râles. The signs over the right lobes varied markedly. At one time breath sounds could hardly be heard and again they were present with little alteration. Wheezing and musical râles were always heard. The signs suggested obstruction of the bronchi of the middle and lower lobes which was not complete and varied from time to time. The tooth was found crosswise in the bronchus just below the orifice of the middle lobe bronchus, which was involved by the swelling of the mucosa. After removal the breath sounds were well heard without any râles. In four days the signs were normal. In this case there was no permanent damage and the patient recovered completely.

A woman, aged 20 years, was admitted on April 17th, 1923, complaining of cough and loss of weight. Three months before she had three teeth extracted under gas and immediately after she stated that she had a choking sensation during the extraction and believed that she had swallowed a tooth. This was laughed at and declared to be impossible. Cough came on immediately after and has grown more severe. The sputum has increased in amount and become foul. The patient did not have any dyspnœa or wheeze, but had a very distressing cough. There was less expansion on the left side with a normal percussion note and harsh breath sounds over the upper lobe. Over the lower left lobe there was dullness, with absence of vocal fremitus and breath and voice sounds. The tooth was found blocking the lower lobe bronchus. Immediately after removal there were many coarse râles heard over the lower lobe. She made an excellent recovery.

The next case shows the results of a long sojourn of a tooth in a bronchus.

A man, aged 51 years, was admitted on April 21st, 1919, complaining of cough, foul sputum, and dyspnœa on exertion. On Nov. 29th, 1914, he had two teeth extracted under ether anæsthesia. He noticed nothing of moment until Dec. 8th, 1914, when he was taken ill with "pneumonia," and spent nine weeks in bed. He had high fever (up to 105° F.) and violent cough with large amounts of foul sputum. A negative exploratory puncture was made during the illness apparently under the idea that he had empyema. After 14 weeks he was able to resume his work. Ever since he has had cough with profuse sputum, foul-smelling and sometimes bloody. His general health has been poor and he has been in bed frequently with fever. On examination the fingers and toes showed marked clubbing. The thorax was rounded and showed very little expansion. On deep breathing decreased movement of the lower right side was evident. The left lung was clear. There was dullness over the lower right lobe and the breath sounds had somewhat of a blowing quality. A few râles were heard on quiet breathing, which were louder and coarser on deep breathing. On bronchoscopy there was a stricture found and many fistulæ lined with granulation tissue. These were dilated and explored. On a second bronchoscopy the tooth was found embedded in tissue without any direct opening to it. When grasped by the forceps the tooth crumbled and only a part could be removed. Two subsequent bronchoscopies were required to remove all the fragments.

Nuts, Grains of Corn, and Vegetable Material.

These organic substances form a most important group as there is always great danger of death resulting in a short time from toxæmia and septic infection, especially in young children. In the United States the peanut is the most common member of this group to be aspirated. It is a common article of diet, and judging from our experience is frequently given to young children either as the nut itself or in the form of candy containing peanuts. In many cases the child is unable to chew the nut and endeavours to swallow a fairly large portion; choking results and the nut is aspirated. To the resulting condition Jackson and Spencer[2] gave the name arachidic bronchitis. It is worthy of discussion in some detail.

Arachidic Bronchitis.—Age is an important factor as the cases are almost always in children and frequently in those below the age of two years. Dr. Jackson has had only one case in an adult and he was a physician. The severity of the resulting symptoms varies with the age; the younger the child, the more severe and dangerous they are. The condition produced is a very remarkable one. There is a most acute œdematous laryngo-tracheo-bronchitis with the formation of thick pus. The rapidity of development of the inflammatory process is remarkable. It may be marked in a few hours. The purulent secretion forms very rapidly, is often extremely profuse, and in some cases is most tenacious, so that moulds of the bronchi form, much like those occurring in fibrinous bronchitis. The process is most marked about the site of the nut or grain, but tends to spread upwards if the nut is in a lower lobe bronchus so that the whole bronchial tree is involved. The bronchi of the other lung also become involved to some extent. The cause of this intense irritation is not clear. Two globulins are found in the peanut, arachin and conarachin, and it has been suggested that these may contain some special irritant.

The effects produced are very striking. There is evidence of severe infection, shown by fever, which is often high, leucocytosis, and severe toxæmia. This latter is usually marked and the picture is sometimes not unlike that seen in malignant diphtheria. Death may follow in a short time if the nut is not removed. Jackson mentions that death occurred in two weeks in three patients in whom bronchoscopy was not allowed. The extreme dyspnœa with infection and toxæmia rapidly exhausts the patients. Striking features are the rapid pulse- and respiration-rates, which remain fairly constant despite variations in the temperature. If the peanut remains for a few days there is the accumulation of enormous amounts of pus below it and the rapid formation of one, or usually many, abscess cavities.

The clinical picture is usually a remarkable one, and the younger the patient the more acute the symptoms. There is great dyspnœa and restlessness with marked cyanosis. There is toxæmia from the septic infection and asphyxiation from the obstruction due to the secretion and swelling of the mucous membrane. In some patients the cyanosis is succeeded by pallor which may be deceptive, for instead of being a sign of improvement it means exhaustion and the approach of death. Cough is frequent and paroxysmal; sometimes a pink purulent sputum is brought up; often nothing can be dislodged. The "asthmatoid wheeze" is frequently present. A point of importance is that the voice is rarely lost. With the marked dyspnœa and asphyxiation the picture is a most distressing one, and much like that of laryngeal diphtheria. The usual signs of obstruction to inspiration are well marked. The physical findings are shown by the report of some cases.

Peanut in Bronchus.—A child, aged 22 months, was admitted on Nov. 6th, 1923, with a history that at 8 A.M. on the day of admission she was eating peanuts. Suddenly she began to cough and became red in the face; wheezing respiration was noted immediately. On admission the child was very restless, cyanotic, and dyspnœic. There was a distinct wheeze with convulsive attacks of coughing. The left side was distended and showed absence of expansion. The note over the left side had a tympanitic quality with absence of the breath sounds. The X ray study showed marked *obstructive* emphysema of the left lung. Bronchoscopy was done the same day and the trachea and both bronchial orifices were intensely red and inflamed. The peanut was removed from the left bronchus a little over eight hours from the time of aspiration. The child did not improve and continued to have fever with signs suggesting the presence of secretion in the lower lobes. Death occurred on Dec. 8th. At autopsy there was marked inflammation in the trachea and bronchi, the mucosa being covered by purulent material. On the right side there was considerable suppuration. Death was apparently due to septic infection.

This case shows the serious results which may follow the aspiration of a nut. The foreign body was removed after being eight hours in the bronchus, but the infectious process set up by it progressed until death resulted. The rapid development of the inflammatory process is to be noted. It suggests an action like that due to an irritant gas. The condition illustrates the *ball-valve action* of a foreign body; air was allowed to pass into the left lung but could not get out. It is very easy in such cases to mistake the affected side unless a careful examination is made. In the next case there was not complete blocking of the bronchus and air could pass in and out.

---

[2] Jour. Amer. Med. Assn., 1919, lxxiii, 672.

Peanut in Bronchus.—A child, aged 2 years, was admitted on Jan. 25th, 1923, with strangling cough and wheezing respiration. On the previous day, while eating peanuts, the child began to cry and there was an attack of strangling and dyspnœa. There was a loud wheeze both with inspiration and expiration and some dyspnœa, but no marked cyanosis. The expansion was decreased on the right side. The left side showed hyper-resonance with harsh breath sounds. Over the right side the note generally had a tympanitic quality with some dullness over the lower back. The breath sounds varied greatly. At times both inspiration and expiration could be heard, accompanied by very curious high-pitched whistling and wheezing râles. The heart was displaced to the left. The signs suggested that the peanut was in the right main bronchus, but was not causing complete obstruction. Bronchoscopy was done at once. There was marked swelling of the subglottic tissues with considerable pus in the trachea and bronchi. The peanut was removed from the right main bronchus. Tracheotomy had to be done subsequently and then followed a struggle for the life of the child which required frequent bronchoscopies, an average of three or four a day for some days, because large crusts formed in the bronchi. These caused marked obstruction and at times air was prevented from entering a whole lung or a lobe by them. On one occasion the child stopped breathing, but fortunately it was possible to remove a large cast of a bronchus at once. Constant aspiration of the trachea had to be done. The condition gradually improved and the child was discharged well on March 15th. Only the repeated bronchoscopies with the removal of the material in the bronchi saved the child's life, as the cough reflex seemed to be completely abolished.

Here, again, the remarkable rapidity of the process is shown. Within about 24 hours after aspiration large amounts of pus had formed. The persistent formation of the "crusts" in the bronchi was an unusual feature.

A very striking feature of the foreign bodies belonging to the vegetable kingdom is the rapidity with which acute inflammatory changes are produced. This is especially true of the peanut, but applies also to other vegetable substances. Beans and grains of corn are not infrequently aspirated, and the following cases illustrate the rapidity with which inflammatory changes follow :—

Corn in Bronchus.—A child, aged 14 months, was admitted on Feb. 25th, 1923, with the history that on the day of admission she was playing with grains of corn (maize) and suddenly began to choke and cough, at the same time becoming very blue. A few hours later she showed great distress, cyanosis, marked inspiratory dyspnœa, cough, and a loud wheeze. At times with the cough there was a distinct slap which could be heard and felt over the larynx. There was well-marked inspiratory retraction both above the sternum and clavicles and in the epigastrium. Expansion seemed equal as a rule, but occasionally one side was limited. Percussion was resonant throughout, and on auscultation the breath sounds were rough and harsh with an occasional shutting off of all breath sounds. Coarse râles were heard on both sides. The diagnosis was made of a foreign body in the trachea which occasionally passed temporarily into a main bronchus. Bronchoscopy was done promptly ; very marked swelling of the larynx and subglottic tissues was found, with marked inflammation of the tracheal mucosa and considerable secretion. The grain of corn was found to be shifting about and was finally removed from the right bronchus. Tracheotomy had to be done subsequently on account of the laryngeal obstruction ; the child made a good recovery.

Bean in Bronchus.—A child, aged 13 months, was admitted on March 20th, 1923, with a history of playing with beans the day before. She suddenly coughed and choked, and when the mother ran to her the child had great dyspnœa and wheezing respiration. On examination the child was very ill, had marked dyspnœa, and a well-marked asthmatoid wheeze. The signs were much as in the previous case. Bronchoscopy was done at once and marked inflammation and considerable secretion found. The bean was found at the bifurcation of the trachea partially in the right bronchus.

Particular emphasis should be placed on the *acuteness* of the symptoms. Within a few hours the child may be in danger of death. In the cases quoted death would have followed very shortly unless the foreign body had been removed. There is no reason to suppose that such cases are only of recent occurrence, and there are no statistics which show the number of deaths from this cause. It must not be supposed that all cases are as acute as those quoted. In older children the picture is much less acute. There must be a great difference in the individual reaction or in the amount of irritation set up by the vegetable substance. This is shown in the following case :—

Peanut in Bronchus.—A child, aged 2½ years, was admitted on June 15th, 1923, with a history of having been eating candy which contained peanuts on June 4th, 1923. A portion was aspirated and following an attack of choking there were cough and distress. The signs showed the nut to be in the left lower lobe bronchus and that the blocking was not complete as the amount of air in the lobe varied from day to day. At bronchoscopy (Jackson) there was a great deal of swelling of the mucous membrane and granulation tissue in the lower left lobe bronchus. Recovery was rapid, and a week after removal the expansion was equal on the two sides.

Miscellaneous Objects.

There are many curious objects which gain entrance to the bronchi, only a few of which can be noted. Fig. 5 shows a broken tracheotomy tube impacted in the left bronchus.

Portion of Rubber in Bronchus.—A boy, aged 5 years, was admitted on Sept. 29th, 1923, complaining of constant wheezing which was greatly increased during sleep. About three weeks before the child was playing with a piece of rubber and suddenly began to cough, saying that the rubber had gone down his throat. Wheezing was noted at once and has continued. The child was not dyspnœic or cyanotic. The wheezing sound was heard occasionally. Inspection showed decreased expansion over the lower right thorax. The note over the upper left lung was slightly hyper-resonant ; over the lower left lung there was slight dullness. There was dullness over the lower right lobe more than on the left side. The breath sounds were generally harsh with coarse râles over the lower left lung. Over the lower right lung the breath sounds were distant and accompanied by coarse, gurgling râles. The signs varied from day to day and were puzzling. We regarded the foreign body as being in the lower right lobe and the signs on the left side as due to secretion which had passed over from the right side. Repeated X ray studies were negative at first, but later the right diaphragm moved less and peribronchial thickening became more marked on the right side. Later there was increased density in the lower right lobe. The first bronchoscopy (Jackson) on Oct. 3rd showed inflammation of the right bronchus with many granulations and some muco-pus. A foreign body was not seen. After this tracheotomy had to be done. At a second bronchoscopy on Oct. 31st, after inspiration of pus and removal of granulations, a small black object was seen which after removal was found to be a piece of rubber. Recovery was rapid ; the breath sounds soon were heard over the lower right lobe, and the child was discharged well.

In this case the diagnosis was only reached after repeated examinations and after the signs in the lower right lobe became more definite. The collection of secretion in the lower part of the opposite lung may be a source of great difficulty, as in this case.

Cork in Bronchus.—The patient, aged 19 years, was admitted on March 8th, 1923, complaining of cough, wheezing respiration, and attacks of cyanosis. On Feb. 12th, 1923, she had a small piece of cork in her mouth about the size of the rubber on the end of a pencil. She laughed and the cork was aspirated. Cough followed at once and has continued with wheezing respiration. A few days later she was supposed to have pneumonia. On admission she had very severe cough and marked wheezing, but not marked dyspnœa. Expansion was less on the right side, especially below. There was some dullness over the middle right lobe and marked dullness over the lower lobe, except for an area of resonance over the lower right back. Vocal fremitus was decreased over the lower lobe. The breath sounds were heard but diminished over the middle lobe. On quiet breathing no breath sounds were heard over the lower right lobe, but on deep breathing they were heard with a number of squeaky râles. Over the upper right lobe there were normal resonance and breath sounds with occasional râles. The X ray study showed marked changes over the lower right lobe. At bronchoscopy (Jackson) the cork was found in the lower lobe bronchus completely surrounded by granulation tissue, which extended up to the orifice of the middle lobe bronchus.

This case illustrates the relationship between the local conditions in the bronchus and the physical signs. The absence of breath sounds on quiet breathing and their presence on deep breathing suggests the presence of granulations which usually extend above the foreign body. The extra effort of deep respiration is sufficient to overcome the obstruction. Signs which are much less marked in a higher lobe, as in this case, suggest granulations which partially obstruct the higher bronchus. The finding of some resonance, often tympany, in the lower back when there is considerable blocking of the lower lobe bronchus is common. The note between the scapular line and the spine may show some resonance—often a combination of tympany and dullness—while from the scapular line to the axilla and in the axilla there is flatness.

Piece of Tin in Bronchus.—A child, aged 11 years, was admitted on Dec. 19th, 1923, with the statement that he had a piece of tin in a bronchus. On Dec. 2nd, 1923, he picked up a piece of tin and put it in his mouth. He laughed and the tin disappeared. For a few days he had a croupy cough which did not continue. Five unsuccessful attempts at removal had been made elsewhere. The child did not have any cough, dyspnœa, or wheezing. There was less expansion on the right side with dullness over the lower lobe, which was least marked between the scapular line and the spine at the base. Vocal fremitus was absent over the lower lobe. Breath sounds were heard distantly over the lower lobe on deep breathing. The signs varied from day to day, and at times over the middle lobe there was some dullness and decreased breath sounds. At bronchoscopy (Jackson) the object was found deep in a lower lobe bronchus. Removal was difficult as a sharp, thin edge at one end had made a cavity by ulceration. Recovery was rapid and he was discharged with normal findings in the lung.

Top of Pencil in Bronchus.—A boy, aged 6 years, was admitted on March 16th, 1920, complaining of cough and dyspnœa. On March 13th, 1920, while holding the metal top of a pencil in his mouth, he fell and the object disappeared. The child choked and strangled for a time afterwards. Dyspnœa and paroxysmal cough followed. The child was very ill and extremely dyspnœic and cyanotic. There was absence of movement of the left side of the chest and the heart was displaced far to the left. There was dullness throughout the left lung, which was less marked over the upper lobe. The breath sounds were heard, intensely tubular with a few râles, over the upper left lobe ; they were absent over the greater part of the lower left lobe, where no râles were heard. Over the lower left back very distant blowing breathing was heard. The X ray showed a dense shadow over the whole of the left lung with the heart displaced to the left. There was evidently collapse of the left lung. At bronchoscopy the body was found in the left lower lobe bronchus, the upper edge almost occluding the orifice of the upper lobe bronchus. It was very tightly impacted. The child was examined at once after the removal of the foreign body. There was resonance throughout the left side with a tympanitic quality. Breath sounds were heard everywhere, over the upper lobe slightly harsh and over the lower lobe harsher than normal and with many coarse bubbling râles. The recovery was rapid.

The rapid change in the breath sounds after removal of the foreign body is of interest. Within two minutes the intense tubular breathing over the upper left lobe was replaced by vesicular breath sounds only slightly harsher than normal. The difference in signs over the upper and lower left lobes is puzzling, as both seemed to be affected. This is noted not infrequently when the foreign body is so situated that it obstructs the lower lobe bronchus completely and the upper lobe bronchus partially. In this case the tubular breathing over the upper lobe might naturally have suggested pneumonia.

Cases of Long Duration.

These are interesting as demonstrations of how tolerant the lung can be of a foreign body. The longest period in Dr. Jackson's series is 36 years (two cases). The foreign body is usually in a lower lobe bronchus and marked changes are always present. Abscess formation, bronchiectasis, and fibroid changes are to be expected. The clinical picture is due to these and does not offer anything peculiar. The general health suffers as from any long-continued lung suppuration, and clubbing of the fingers and toes is common. In some of the patients a diagnosis of tuberculosis is made for which there is little, if any, excuse. In some an X ray study done by a physician newly consulted has given the diagnosis. The following case illustrates many of the features :—

Nail in Bronchus.—A boy, aged 12 years, was admitted on Nov. 27th, 1922, complaining of wheezing respiration and occasional cough. On Sept. 20th, 1912, he had a number of shingle nails in the mouth and in falling aspirated one of them. No clear account of the following symptoms could be obtained. In November, 1912, he was supposed to have an attack of pneumonia and several illnesses since then were also diagnosed as pneumonia. He has had wheezing respiration since the aspiration and some cough, always worse on violent exertion. An X ray plate was taken after many years of symptoms and the presence of the nail discovered. Six unsuccessful attempts at bronchoscopy had been made elsewhere. The boy was well nourished and did not show any dyspnœa or wheeze when quiet. The sputum was profuse and foul. Expansion was almost entirely absent over the left side except at the apex. Vocal fremitus was present over the upper lobe and absent over the lower lobe. There was dullness over the left side, more marked and with greater resistance over the lower lobe. Over the upper lobe the breath sounds were harsh with prolonged expiration and an extraordinary number of râles. Over the lower lobe the breath sounds were hardly heard, but there were a large number of râles. The heart was displaced to the left. The X ray study showed an apparent absence of normal lung tissue in the left side and many cavities. The nail was found in abnormal tissue. The cough and sputum decreased greatly, but the signs in the lung did not alter materially.

Complications.

Considering the severity of the symptoms in many of the cases and the long duration of bronchial infection these are relatively few. Abscess and bronchiectasis may be regarded more as sequels than as complications. They offer no special peculiarity and have much the same features as when they occur from other causes. The formation of a bronchial stricture is not uncommon. This may interfere with drainage and add to the difficulty of removal of the foreign body. The long-continued suppuration may be accompanied by disturbance of the general health and clubbing of the fingers.

Pneumothorax.—This usually occurs in very acute cases in which presumably there is rupture of an air vesicle from the severe paroxysms of coughing. Its occurrence adds to the severity of the dyspnœa and complicates the diagnosis, difficulty in which evidently occurs particularly in non-opaque foreign bodies. Careful judgment is necessary to decide when bronchoscopy should be done if it seems justified for diagnosis or is indicated for removal of a diagnosed foreign body. Constant watch should be kept to recognise the presence of pyo-pneumothorax. It is evident that no rules can be given as to diagnosis in these cases, and in the absence of any suggestive history of aspiration of a foreign body it may be very difficult. The X ray study is definite in the case of an opaque foreign body. An escape of air into the mediastinal tissues is not very uncommon and does not appear to be of serious import.

Empyema.—This is rare but has occurred in a few cases with a long sojourn of the foreign body in bronchus and abscess formation. The supposition is that infection of the pleura occurs by extension from the lung. The recognition of this complication is usually not difficult by the physical signs, and if necessary aspiration removes any doubt. A difficulty is in the decision whether the foreign body should be removed before draining the empyema. As these patients are usually very toxic and seriously ill, our usual practice has been to drain the empyema first. An illustrative case is as follows :—

A boy, aged 8 years, was admitted on Dec. 5th, 1923, complaining of cough. Six years before he was running while holding a small staple in his mouth. In some way he aspirated the staple. The physicians who saw him made a diagnosis of diphtheria and his breathing became so difficult that tracheotomy was done. After two weeks the acute features disappeared, but some dyspnœa remained and cough has continued to the present. In the past year the child has been losing weight. Finally, an X ray plate was taken, which showed the foreign body. (Fig. 6.) The child was very ill on admission, emaciated, and anæmic. He had a hoarse cough but no wheeze. The left chest showed absence of expansion and flatness over the lower part with dullness above. There was marked resistance over the lower part. The breath sounds were not heard. The right side was hyper-resonant and the breath sounds were harsh. The heart was displaced to the right. The X ray study showed a staple in the left bronchus and a thick shadow throughout. By an exploratory puncture thick pus was obtained. There was an irregular temperature curve, the maximum being

103° to 104° F. It was decided to drain the empyema first, and this was done. The child did very well and improved steadily. On Dec. 5th the foreign body was removed. The left bronchus contained many granulations. The child was discharged on Dec. 22nd greatly improved, but with signs of extensive change in the left lung and thickening of the pleura.

Hæmorrhage.—Small amounts of blood may be brought up soon after the aspiration, but profuse bleeding usually occurs after a long sojourn of the foreign body in the lung. An object with a sharp edge may erode the mucous membrane and bleeding occurs from the ulcer produced. With abscess or bronchiectasis the hæmorrhage may be in large amounts and death may result from it. In one patient admitted to my service a scarf-pin had been in the lung for 36 years and a squamous-celled carcinoma developed. The foreign body was recognised and bronchoscopy done, much foul pus being removed, but the bronchoscopy was not prolonged on account of her condition. She died four days later from a profuse hæmorrhage. The case has been reported by Weiss and Krusen.[3]

Goulstonian Lectures

ON SOME

WASTING DISORDERS OF EARLY INFANCY.

Delivered before the Royal College of Physicians of London

By LEONARD G. PARSONS, M.D.,
F.R.C.P. Lond.,

(*With Charts on Plate.*)

LECTURE II.

Delivered on March 27th.

It is frequently found that atrophic children do extremely well for a time when fed on a low fat dietary—e.g., skimmed milk or a mixture of whole and skimmed milk—particularly if there has been diarrhœa. If these cases are followed up, after a time the gains become less; later the weight curve becomes horizontal, or even shows a downward tendency. If, however, the fat content of the food is increased, the weight curve ascends again. These facts are, of course, exactly parallelled by well-known experimental results. Thus, if a diet lacking in vitamin A is given to young growing rats, growth, under favourable conditions, may continue at a nearly normal rate, due presumably to using surplus vitamin A in the body, until the supply is exhausted, when growth slackens and usually ceases. Often a rather rapid loss of weight begins shortly afterwards, and the animal goes into a condition of general decline, leading to death. If vitamin A is given growth is renewed. In milk vitamin A is divided about equally between the fat globules and the aqueous part; in other words, skimmed milk contains only about one-half the vitamin A present in whole milk (McCollum).[1]

Recent Experimental Findings on Vitamin-A Deficiency.

Some further experimental findings on vitamin-A deficiency, which may prove to be of importance in infantile atrophy, have recently been published. By feeding young rats on a diet deficient in vitamin A, Cramer[2] found that atrophy of the intestinal mucous membrane occurred, with an increase in bacterial content of the intestine, and evidence of the invasion of the villi with bacteria. Gross[3] found that when adult rats were fed on such a diet, there was a marked acceleration of the passage of food through the alimentary canal. The latter observation may help to explain the clinical fact to which I have already drawn attention, that in some atrophic infants the passage of food through the alimentary tract is much more rapid than in others. Increase in bacterial content of the intestine also occurs in atrophic children under certain conditions, but up to the present there has been no real evidence of the occurrence of atrophy and consequent loss of absorptive power of the intestinal mucous membrane. Gross did not find any intestinal atrophy in his animals, but it is probably unfair to compare the two sets of experiments, for in one the deficient diet was kept up for a longer period and young rats were used, whereas in the other the animals were adults.

Following the important observation of Gowland Hopkins[4] that oxidation destroys fat-soluble A, McCollum, Simmonds, Becker and Shipley[5] have found that it is possible to prove the presence of two substances in certain food fats. One of these is fat-soluble A, and the other, a substance which regulates calcium metabolism. Butter fat is a better source of the fat-soluble A than of the other substance, whereas cod-liver oil is a good source of both. They discuss the possibility of both these substances being actually two properties of one and the same substance, but their view is quite definitely that there are two distinct substances, "a special calcium depositing vitamin which is often associated with fat-soluble A, but is distinct from it." They demonstrated the absence of fat-soluble A in the food fat by its inability to effect a cure of xerophthalmia when given to animals in which this condition had been experimentally produced; and the absence of the calcium depositing vitamin, by the inability of the food fat to produce a "white line" in X ray negatives, when given to rats previously rendered rachitic by dieting. The "white line" is a line of deposition of calcium salts running transversely across the cartilage, which is produced when food containing fat-soluble A in any quantity, and, according to these researches, the calcium containing vitamin also is suddenly introduced into the diet of a rachitic rat. These observations, which have been confirmed by Steenbock, Hart, Jones, and Black,[35] are of considerable importance with regard to the rôle of fats in infantile atrophy and infant feeding generally.

The condition of xerophthalmia is very rarely seen in the children's clinics of this country. During the last 13 years there have been only 13 cases of the mild form of xerophthalmia—i.e., xerosis of the conjunctiva—seen at the Birmingham and Midland Eye Hospital, and not one case of the severe form of the disease keratomalacia. On the continent, and particularly in Denmark, during the period of the war the disease has been observed much more frequently. Bloch[6] tells us that although he had seen xerophthalmia in Denmark from 1912 onwards, during the war the number was greatly increased. Denmark is a dairy-farming country which manufactures and exports butter. During the war, owing to the blockade, the prices of butter and fresh milk rose so high that the poor could scarcely procure either of them. Buttermilk and separated milk could, however, always be obtained at a low price, and were therefore largely used for the artificial feeding of infants. In some cases an excess of carbohydrate food was given, either alone, or in combination with separated milk. As a result of these methods of feeding, Bloch was able to recognise two groups of cases, in both of which xerophthalmia occurred. He labelled these dystrophia alipogenetica and dystrophia amylogenetica, respectively. To the latter group of cases I will refer later. In dystrophia alipogenetica the growth of the child stopped, there was some wasting, and xerophthalmia developed. The proof that these symptoms were due to the absence of fat containing fat-soluble A occurred when the Danish Government took over the control of butter and rationed it, allowing 250 g. weekly to each adult and child. Xerophthalmia ceased simultaneously. The rationing of butter came to an end after the termination of the war and xerophthalmia recurred, but its occurrence was rare in comparison with the war period, and the severe cases were no longer seen. In Germany during the war xerophthalmia was scarcely ever seen, due to the fact that all the milk and milk products were rationed, so that every little child obtained a certain amount daily, or if the child was breast-fed, the mother was allowed the milk. Bloch made an observation which is of considerable interest in the light of the experiments of McCollum and his co-workers—namely, that xerophthalmia and rickets were very rarely met with in the same child.

CALCIUM METABOLISM IN ATROPHY.

The literature on the subject of calcium metabolism, and its relation to fat is very extensive, and many diverse views are expressed. Some believe that a high fat intake results in a large fat excretion, accompanied by a serious loss of bases, especially calcium (Czerny). Others believe that a liberal intake of calcium, which is frequent in children fed on cows' milk, results in an excessive excretion of calcium, which is accompanied by a harmful loss of fat; or the excess may be "ingested, entering the body fluids and tissues in organic combination and perhaps subsequently setting up a toxic condition."[7] Others again (Holt) say that there is no evidence of these results, and believe that an ample intake of both fat and calcium produces only beneficial results.

With the exception of Utheim's[8] series of 17 cases, I know of no extended observations on calcium metabolism in infantile atrophy. In 39 of my cases in which fat estimations of the stool were done, observations on calcium metabolism were also made. The stools were ashed, and calcium was determined in the weighed ash by the McCrudden[9] method. This is the method used by Utheim and also by Holt, Courtney, and Fales, who investigated the calcium metabolism in a series of normal children, children suffering from diarrhœa, and children suffering from rickets. According to the latter workers, calcium metabolism results are only truly comparable when the same methods are used.

Calcium has not been estimated in the urine, so that the observations do not give absolutely definite "balance" figures, but all observers agree that the amount excreted in the urine is very small (less than 4 per cent. according to Findlay, Paton, and Sharpe[10]), and the omission of urinary calcium does not therefore affect the figures very much. From our observations we have found that calcium output varies fairly closely with the weight of the dried fæces; this is so not only when comparing different children, but also in the daily variations of calcium output and fæcal weight in the same child. From a consideration of Chart 1 (see plate) it will be seen that the curve of the output of calcium follows the curve of the intake, but only in a very general fashion, and that there are many exceptions. I would draw attention to the occurrence in one case of an output greater than intake (negative balance), and to at least four other cases in which the output closely approximates to the intake. The output of calcium follows more closely the intake of fat than the intake of calcium, provided that the fat intake is not less than 12 g. daily. When the fat intake is less than 12 g. daily, the calcium output shows no constant relationship to it, indeed, in several cases the calcium output is relatively and absolutely greater than in many cases having a higher fat intake.

The best absorption percentages were found when the fat intake was more than 2·5 g. per kg. of body-weight, and more than 0·19 g. of calcium per kg. of body-weight.

A comparison of different methods of feeding, to determine their calcium value to the atrophic child, is of interest. From Chart 2 it is seen that a variety of dried cows' milk made by the roller process shows a high amount of calcium absorbed, whereas a dried humanised milk, prepared by the spray method, shows a much lower amount absorbed. The ordinary cows' milk mixtures give an intermediate value. The possibility of the endogenous origin of some of the calcium in the fæces must, however, be borne in mind in assessing the value of these results, although the actual amount of the calcium intake in these feeds does vary in a similar fashion.

The actual figures obtained by us, and how they compare with those of other observers, can be seen from the table.

—	Holt, Courtney, and Fales: Bottle-fed infants, not atrophic.	Utheim: Atrophic infants.	Parsons and Hickmans: Atrophic infants.
	30 cases, ages 2–16 mos.	28 obs., 17 cases, 3 wks.–14 mos.	39 cases, to 6 mos.
Average absorption of CaO per kg. of body-weight.			
Average .	0·081 g.	0·067 g.	0·121 g.
Range ..	−0·064 to 0·133	−0·48 to 0·309	−0·02 to 0·335
Percentage absorption of CaO.			
Average .	37·2 %	24·9 %	43·3 %
Range ..	0 to 66·7 %	0 to 68·5 %	0 to 87·8 %
Daily total excretion of CaO.			
Average .	0·75 g.	0·71 g.	0·59 g.
Range ..	0·34 to 1·58 g.	0·125 to 2·136 g.	0·09 to 1·60 g.

Prior to Holt's paper, the recorded observations on calcium metabolism showed very much lower values for the absorption per kg. of body-weight, the actual figures for children under six months fed on cows' milk being 0·002 g. to 0·06 g. It is possible that differences in the method of estimating calcium may account for this. The figures, however, in the above table are all strictly comparable, since the same methods were used in each series of cases. Findlay, Paton, and Sharpe[10] state that infants under one year absorb 35 per cent. of the calcium intake. This value is, however, based on three cases only, the youngest being aged 6½ months. This child is the only one comparable with my cases, and it showed an absorption of 0·178 g. of calcium oxide per kg. of body-weight, or 56·4 per cent. of the intake.

By means of Chart 3 (see plate) I have compared the calcium output with the amounts of soaps found in dried fæces, from which it is evident that there is no definite parallelism between the excretion of calcium and the excretion of soap, although the curve of calcium excretion does rise with the highest readings for soap. In four instances it is interesting to note that the amount of calcium found in the fæces is greater than the amount of soap; this is probably due to the presence of calcium phosphate and calcium carbonate. These cases occurred in children who were on a very low fat diet, and the relatively high excretion of calcium may possibly be associated with the absence of a calcium depositing vitamin.

The amount of calcium lost as soap does not usually form a large proportion of the calcium intake; indeed, it has been stated that it probably does not amount to 30 per cent. (Holt). In our cases the average has been even less—namely, 17 per cent.—but one case showed the high figure of 65 per cent., and in this instance once again the baby was receiving a high fat content dried milk. The influence of calcium soaps on the daily fæcal weight is, according to Telfer,[11] considerable; this is so, not because of their own weight, but because they apparently have the property of occluding or incorporating the constituents of the intestinal contents in amounts proportional to their mass. This observer also states that he was unable to find any evidence of an appreciable degree of endogenous calcium in the fæces; Hamilton,[12] on the other hand, in a recent paper on the calcium metabolism of premature infants, advances the view that "probably the calcium soaps present in the fæces are to be regarded as a secondary product after the calcium has passed through the internal metabolism, when it is excreted into the intestine." The existence of a negative calcium balance, found by us in one case, and also by other observers, is difficult to explain in the absence of endogenous calcium in the fæces. The finding of low retention values for calcium, when the intake of calcium and fat is sufficient, also suggests the probability of the presence of endogenous calcium in the fæces.

Our results, therefore, show that many atrophic children can absorb calcium as well as normal children; and, indeed, that, as with fat, many are actually able to absorb larger amounts per kg. of body-weight than the amount usually absorbed by the atrophic child. These experimental results support the view that in atrophy an ample intake of fat and calcium produces only beneficial results, and that if feeds low in fat, or low in calcium, are given over a long period of time, the calcium retention may reach a dangerously low level. They also show that in atrophy low retention values and even a negative calcium balance may occur.

THE METABOLISM OF CARBOHYDRATES IN ATROPHY AND CARBOHYDRATE INDIGESTION.

In my first lecture I quoted Finkelstein's views on the harmfulness of lactose, and gave an account of the criticisms advanced against this view; actually in more recent years he has retreated somewhat from his original position, and has stated that considerable quantities of carbohydrate can be added to protein milk. I have also referred to the fact that, during the war period, Bloch[6] was able to separate a group of cases to which he gave the name dystrophia amylogenetica, and which are due to the giving of food containing an excess of carbohydrate, but showing an almost complete absence of fat. These cases presented the picture of Mehlnährschaden, the tissues of the child were œdematous, there was marked hypertonicity, as evidenced by the hands taking up the position known as "paw-hand" and by rigidity of the neck, xerophthalmia developed, and the children became very susceptible to infection. Later the dystrophy passed on to actual atrophy. Bloch thinks that the atrophic form is more likely to occur when new-born and delicate babies are fed for a long time on this type of food, whereas the hydræmic form is more likely to occur if the child is a few months old, and particularly if it was a strong child when the excessive carbohydrate feeding was started.

Photographs of these children show that the picture of carbohydrate atrophy is, with the exception of the state of the eyes, similar to that of the wasted hypertonic infant not infrequently seen in this country, even when there has not been excessive carbohydrate feeding. The picture of carbohydrate dystrophy shows œdema similar to, but more marked than, that which is also seen in this country characteristically associated with high carbohydrate feeding. Œdema, however, does occur apart from this form of diet, and for which there does not appear any obvious explanation, unless, indeed, it bears some relationship to the varying salt content of the whey as suggested by Finkelstein.

The blood-sugar of atrophic children has been shown by several investigators to be below normal; this also obtains in pyloric stenosis when wasting has occurred, as demonstrated by Barling and myself.[13] The sugar tolerance (the metabolic tolerance for sugar) of atrophic infants is very high (Helmholz and Sauer[14]); by giving a continuous intravenous injection of dextrose at the rate of 25 to 50 c.cm. per hour, Matill, Mayer, and Sauer[15] found that the tolerance of normal children is practically that of adults—namely, 0·8 to 0·9 g. of dextrose per kg. of body-weight per hour; whereas that of atrophic infants is considerably greater—namely, 1·4 to 1·8 g. per kg. per hour. Fleming[16] gave glucose by the mouth to atrophic infants and found that 3·0 g., in one case even 6·6 g. per kg., of body-weight could be tolerated without producing glycosuria. The limit of tolerance in adults is about 2·5 g. per kg. of body-weight. The same observer examined the respiratory exchange in atrophic infants and found that their respiratory quotients do not suggest that their tissues are unable to utilise either fats or carbohydrates.

From a consideration of the literature and the result of his own experiments, Fleming concludes that atrophic children use sugar extravagantly, and are in a state of sugar starvation, the result of failure of the digestive processes. He says: "Evidence is brought forward which suggests that failure to thrive is not caused by inability of the organism to utilise any of the proximate principles of food, but rather by gastro-intestinal disturbances, leading to defective absorption, especially of carbohydrates." He is supported in this view by Guy,[17] and this presumably can be taken as representing the view of the pathogenesis of atrophy held by the Glasgow school.

It is, of course, universally recognised that gastro-intestinal disturbance is common in atrophy, and statistics have been already given on this point, but quite a large number of cases of atrophy do develop without any gastro-intestinal disturbance. If considerable amounts of sugar are given by the mouth, alimentary disturbance (fermentative diarrhœa) is frequently set up, and the only method (except intravenous or intraperitoneal injection of glucose) of giving a considerable amount of carbohydrate to satisfy the increased demand is to use a less easily fermentable sugar, such as dextrimaltose. It is highly probable that even in the normal child a certain amount of sugar is split up by bacterial activity; in children with nutritional disorders, however, the work of Bessau and Bossert[18] shows that an invasion of the upper intestinal tract by *Bacillus coli* definitely occurs. Metabolism absorption experiments therefore will not yield results comparable with the results obtained with fat, but if Fleming's view be correct one would expect to find an appreciable quantity of sugar in the stools in cases not complicated by diarrhœa. Utheim[8] examined seven athreptic infants, five of them over five day periods, and found that the sugar output was very small in all cases, not exceeding 1 per cent. of the intake, regardless of the consistency of the stools. It is worth noting that one of the infants was fed on a food containing 12·4 per cent. of sugar. She also quotes some findings by Usuki, who examined eight children, three of them being atrophic; the sugar output in all the cases varied between 0·1 per cent. and 1·9 per cent. of the intake, and it was not present in the atrophic infants in greater amounts than in the normal children.

These results certainly suggest very strongly that absorption of carbohydrates is not faulty; moreover, there is another and more probable explanation of the sugar starvation—namely, that absorption of carbohydrate is not abnormal in atrophy, but that there is excessive oxidation of sugar in the body and a depletion of the glycogen reserve. Certain of Fleming's results and calculations appear to me to support this view, rather than the one he enunciates.

A few metabolism experiments have been carried out on my cases. The sugar was estimated in the food and in the fæces by Schaffer and Hartman's method. The estimations were carried out over five day periods and the children were not suffering from diarrhœa. The absorption figures in all the cases (six in number) have been very high ones, the average figure being 99·79 per cent.

The results of these absorption experiments support the view that, in the absence of diarrhœa or loose stools, the digestion and absorption of carbohydrates in infantile atrophy is normal. Carbohydrate indigestion, the result of the fermentation of sugar, does, however, occur, and the stool then becomes acid, loose, and green, and may also show mucus and possibly soap curds. The child suffers from vomiting, has colic, and develops sore buttocks. If the indigestion continues, diarrhœa is likely to occur, and then fat absorption is diminished. As a result of these symptoms the already atrophic child becomes more wasted. Carbohydrate indigestion is more frequent than any other form of indigestion, and occurs particularly when the carbohydrate content of the food is high, unless the sugar given is one of the less fermentable forms—e.g., dextrimaltose. This form of indigestion is very similar to the description of Mehlnährschaden by Czerny, and to the carbohydrate atrophy of Bloch, although the carbohydrate is not usually used in this country in the excessive amounts described by these writers. The hypertrophic form of carbohydrate dystrophy is occasionally seen, and when this is the case the child has usually been fed on proprietary foods. The severe types of this form of indigestion appear to be much more rarely seen in this country than on the continent. The treatment of this form of indigestion is, essentially, the limitation of the amount of carbohydrate used, and the substitution of a less fermentable type of sugar—e.g., dextrimaltose, &c.—for that previously used. For this purpose, if the child has been fed on proprietary food it is advantageous to change to a cows' milk mixture. On rare occasions it has been found necessary to give the food without any added sugar until the symptoms have improved. If diarrhœa occurs the treatment already outlined for fat indigestion should also be carried out.

THE METABOLISM OF PROTEIN IN INFANTILE ATROPHY AND PROTEIN INDIGESTION.

I have previously referred to the fact that Biedert, in 1869, first propounded the theory of the harmfulness of protein, and this theory has been disproved by Czerny, Finkelstein, and others; indeed, the pendulum of opinion has swung to the opposite extreme, and protein has been regarded as the one factor that does not lead to infantile atrophy, and the only factor in the food which many atrophic children can adequately deal with; hence the introduction of protein milk. I have used protein milk made by Finkelstein's method, with the exception that ordinary milk has been substituted for buttermilk. I have also used protein milk made by the addition of calcium caseinate "Casec" Mead) to cows' milk. Both these methods have yielded good results in atrophy, particularly when fermentative diarrhœa was present; but it has been my experience that this method of feeding is only a temporary expedient, for after a time loss of weight occurs again, and also in not a few cases hard protein curds appear in the stools, a true protein indigestion. Possibly this failure to continue the initial improvement is due to the alteration in proportion of fat to protein in protein milk, for it has been suggested by Maignon[19] that unless fat is present in the proper proportion, protein is not economically utilised and toxic products are formed.

The well-known observations of Gowland Hopkins, McCollum, Mendel and Osborne, &c., have completely altered earlier views as to the relationship of food protein to growth and the maintenance of life. Food protein is made up of a large number of radicles of amino-acids into which it is broken down during digestion; after absorption a certain number of these are built up again in the body into tissue proteins. Since the tissue proteins do not show the same proportion of amino-acids as the food protein, a certain number of the amino-acids in the food are not utilised, and these are used largely to provide energy being broken down into urea.

The proportions of the amino-acids in different foods varies considerably, but certain of them are essential for growth; in particular lysin, cystin, and tryptophane. Metabolism "balance" experiments may show good results, the animal showing a good nitrogen absorption and retention, yet in the absence of growth amino-acids there will not be any growth. Casein is a poor growth protein because it is very deficient in cystin; lactalbumin, on the contrary, is very efficient and contains of all proteins the highest proportion of leucin, lysin, and tryptophane (Holt),[20] and sufficient cystin to meet the demands of the growing tissue (McLeod)[21]; indeed, it appears to be the most efficient in supporting growth of all the proteins studied. The intake of protein in normal breast-fed children up to 9 months of age is about 1·5 g. per kg. of body-weight (Holt). Bottle-fed children of the same age, as is well known, take much larger quantities than this, the amount being 3 to 4 g. per kg. of body-weight. The increase in protein requirement is probably due to the different amino-acid content of the two milks (Holt), for it should be remembered that whereas lactalbumin forms two-thirds of the protein in human milk, five-sixths of the protein in cows' milk is casein.

In spite of the commonly accepted view that protein can do no harm, the possibility that atrophy may be due to the absorption of unaltered or slightly altered protein has been considered by several writers. Moro[22] found precipitin to cows' milk in blood removed at autopsy from two atrophic infants; Bauer[22] in four cases. Lust[22] showed that under certain conditions the intestinal tract was permeable to egg-albumin, and that this was most frequent in marasmus (decomposition) and diarrhœa (intoxication). This subject has recently been further investigated by Anderson and Schloss[23]; they point out that to cause a specific reaction in the organism protein must be absorbed in a form unaltered or only partly altered by digestion, since protein which has been digested as far as the peptones does not cause specific immune reactions. They examined the blood of 98 marasmic infants, and found that the blood of most of these contained precipitin to cows' milk. They also found that these infants were "apt to show precipitin to cows' milk in their blood only at the time when they begin to gain in weight, and that after a period of gain the precipitin disappears." They suggest that during the period when the infant fails to gain, foreign protein may be entering the blood in sufficient amounts to cause disturbance. Precipitin may be gradually formed as a result of this, and when in sufficient amount neutralises the effect of the foreign protein, and a gain in weight results. With the improvement in the patient's condition the intestinal tract becomes impermeable to undigested or incompletely digested protein, and the precipitin disappears from the blood. They admit that the reaction may be merely indicative of the incidental entrance of foreign protein into the blood-stream owing to a temporary change in the intestine, and be of no special ætiological significance. It is interesting to note that control tests carried out by them on new-born breast-fed children were all negative.

If, as I believe, the view is correct that infantile atrophy is a disorder of metabolism, it may well be that the intestinal mucous membrane shares in the "metabolic depression," becomes more permeable, and that the digestive processes are not properly carried out. Under such conditions absorption experiments would not be of any value in an attempt to prove or disprove this theory. It will be remembered that Finkelstein claims that the whey salts render the intestinal mucous membrane more permeable to sugar and salts, but that this view has not been substantiated, nor is there any evidence of the permeability of the intestinal wall to neutral fat.

Now if digestion is impaired it must, in the absence of diarrhœa, be due to defective ferment activity. It has already been demonstrated that there is not any deficiency of pancreatic lipase, which should be the case if there is enzyme deficiency, and it is surely a reasonable assumption that the other pancreatic ferments are also normal. I have not attempted to estimate the activity of pepsin in infantile atrophy, but it has been asserted that the secretion is somewhat diminished. Gastric digestion in infants fed on cows' milk is however often poor, because, owing to the high buffer value of cows' milk, the requisite hydrogen-ion concentration for pepsin activity is only reached after a considerable period. If the requisite hydrogen-ion concentration occurs in the normal time gastric digestion also appears to be normal. I propose later in this lecture to refer to observations on gastric acidity and hydrogen-ion concentration of the gastric juice and their application to treatment. Attempts to estimate rennin have been made, but from what is said later it will be seen that it is impossible to make any dogmatic statement about this ferment.

PROTEIN ABSORPTION.

A certain number of investigations have been undertaken to determine the protein absorption. The estimation of nitrogen by the Kjeldahl method has been carried out in the moist, and not in the dried fæces, because Gamble [24] has shown that up to 20 per cent. of the nitrogen in the stool may be lost in the process of drying. The estimations have been done in 24 hours specimens of stools, and the stools have been kept in an ice-box until the estimation was started. The estimations were carried out over a period of five days. The percentage absorption of nitrogen varied from 57·7 to 85·8 per cent.; the average for six cases was 77·3 per cent. Utheim,[8] in a series of 30 cases, found the average absorption was 73·8 per cent. Our results are only few in number, and I regret that I cannot give larger numbers, but the number of observations required to get even one result is so large and the amount of time occupied so great, that it has been only possible up to the present to put on record a limited number of observations. I hope that in the future Miss Hickmans and I shall be able to record a larger number of observations, because we found, during the investigations on fat and calcium metabolism, that dogmatic statements cannot be made unless the number of observations is a large one. However, as the results obtained up to the present confirm those of Utheim, they are probably correct. The results are strictly comparable, because the methods of investigation have been the same in both cases, whereas earlier investigators appear to have made nitrogen determinations on dried fæces, and usually to have made only one determination on the whole of the fæces collected during the experiment (Utheim). Our results show that, as in fat and carbohydrate, protein absorption also is normal in infantile atrophy.

Clinically, protein indigestion occurs very rarely, much more rarely than carbohydrate or fat indigestion, and in my experience has only occurred when an excess of protein is given in the food over a considerable period; its treatment therefore consists in feeding with cows' milk modification without the further addition of protein. Citration of the milk may also be useful in this condition.

It is probably unnecessary to add that in referring to treatment of these various forms of indigestion I have assumed that breast milk is unavailable. I might perhaps also add that in my experience the best results have been obtained by simple modifications of cows' milk.

INVESTIGATION OF GASTRIC SECRETION IN ATROPHY.

During the last three years a considerable number of test-meal observations have been made in infantile atrophy and pyloric stenosis, both by the Ewald method and by the fractional test-meal method. In all, some 50 examinations have been made by the latter method. The test-meal itself has varied; in the majority of cases it has been a 2 oz. meal consisting of equal parts of milk and water; in a few cases Meyer's barley gruel test-meal has been used,[25] but recently the practice has been to give the ordinary meal which the child is taking, since that probably gives a more accurate idea of what is happening in the child's stomach than the results obtained by suddenly changing the food, although the change may be to a standard meal.

The interval between the giving of the test-meal and the previous meal is three hours. I should like to have made this a longer period, but considering that the child does not get a full feed for somewhat over six hours, I have felt that, dealing as I have been with atrophic children, it would be unwise to give a longer interval. The food has been withdrawn every half hour, since it has not been found practicable to remove the contents at 15-minute intervals. The contents have been removed with a syringe and No. 6–7 Jacques soft rubber catheter. These investigations were started to determine whether it were possible, by means of a study of gastric secretion, to define certain clinical groups of wasting babies, as, for instance, the constant association of hyperacidity with pylorospasm. It may be stated at once that no such classification of infantile atrophy is possible.

The rate of emptying varies. The average time appears to be between two and two and a half hours, but in some cases it has not been possible to recover any milk later than half an hour after feeding. Cowie and Lyon [26] found that a prolonged emptying time of the stomach occurred with an excess or a deficiency of acid; whereas Babbott and others [27] state that the greater the acidity the more rapidly the stomach empties; and Marriott and Davidson [28] found that in general in infants with a deficiency in gastric acidity, a larger amount of the feeding could be recovered two hours after a meal than in those with an acidity approximating to that of normal breast-fed infants. As a general rule, I believe that the latter two groups of observers are right, but there are many exceptions. Cowie and Lyon's observations of delayed emptying with an excess of acid may possibly have been examples of the hyperacidity which occurs in some forms of pylorospasm.

The value for free hydrochloric acid is a variable one, but in a few cases no free hydrochloric acid was present during the whole period of time during which the food remained in the stomach. This is not a new observation; thus Chievitz,[25] in a recent paper, states that in children with alimentary disturbances more than half show low or absent free hydrochloric acid, and although weights are not given, this group includes cases of dystrophia alipogenetica and amylogenetica. Marriott and Davidson agree that acidity of gastric contents of infants suffering from nutritional disturbances is distinctly lower than in normal infants. Babbott and his co-workers say that artificially-fed infants produce only a small amount of hydrochloric acid during digestion, and the amount is not sufficient to show free hydrochloric acid. This, however, is not consistent with my results, since free hydrochloric acid has been present at some time during digestion in the great majority of cases.

The action of hydrochloric acid in digestion is due chiefly to the number of free hydrogen-ions present. Rennin acts best between pH 6·3 and 6·0. Pepsin, however, requires a greater degree of acidity, and does not begin to act until pH 5·0 reaching half activity at pH 4·0, and full activity at about pH 2·5. It is therefore obvious that if there is not enough hydrochloric acid secreted to bring the stomach contents to the requisite degree of acidity, gastric digestion cannot take place. The acidity may be low, either as a result of deficient secretion or because the acid secreted is neutralised by the food. The (alkali) buffer value of the various foods given is, therefore, of considerable importance, and as previously stated, the buffer value of cows' milk is a very high one.

It is interesting to compare the amounts of decinormal hydrochloric acid which it is necessary to add to various foods to bring their acidity to pH 5·2–5·4.

	c.cm.		c.cm.
Breast milk	1·3	Almata (1 in 8)	1·0
Cows' milk (undiluted).	3·3	Humanised (Trufood, dried)	3·1
Nestlé's (1 in 8)	2·7	Allenburys No. 1.. ..	3·1
Glaxo—full cream. ..	2·8		
Glaxo—half cream ..	2·7		

It is important, therefore, to reduce the buffer value of cows' milk, particularly when it is given to infants suffering from nutritional disorders. This may be done in several ways; it can be done by diluting cows' milk, but the dilution must be considerable, a dilution of one of milk to three of water having about the same buffer value as breast milk. From the figures just given it will be seen that by drying cows' milk the buffer value is diminished. Another method is to saturate the buffer with acid. Thus Faber [29] has recently suggested the addition of hydrochloric acid to cows' milk, and Marriott has for some time used lactic acid for the same purpose, and has reported very good results with this method of feeding. Protein milk may owe much of its value to the fact that it has a low buffer value.

The results obtained by metabolism experiments justify the conclusion that digestion is normal in atrophy in the absence of diarrhœa. Now if the degree of gastric acidity is insufficient to activate pepsin and rennin, it follows that more digestion is carried out in the small intestine than in those cases in which the gastric ferments are activated. This, together with the fact that in the partial or complete absence of hydrochloric acid bacterial invasion of the duodenum is more likely to occur, may be an explanation of the onset of some cases of diarrhœa in atrophy.

I have not used Marriott's lactic acid milk in cases of infantile atrophy, but I have used hydrochloric acid in the amounts suggested by Faber and with good results. To every ounce of milk is added 2 dr. of decinormal hydrochloric acid and 2 dr. of water. The addition of this amount of acid gives approximately a pH value of 6·0; the buffer value is about that of breast milk, and therefore the demands on the child's stomach for acid is equivalent to that of breast milk. Normally, such an addition of hydrochloric acid does not produce any appreciable alteration in the taste, nor is there any curdling. It is obviously important that the acid should be added to the milk and not milk to the acid, because in the latter case curdling will immediately take place. I have found that occasionally milk is curdled with this amount of acid; this is probably due to the fact that lactic acid formation has progressed to such a degree that by the addition of more acid the acidity is raised to the point when curdling occurs. The milk should therefore be as fresh as possible. Another practical point is that curdling is often prevented if the feed when being warmed is not made too hot.

I have not used this method of feeding in children under three months, and Faber does not recommend its usage in the first six weeks of life, his main reason for this being that breast milk is fairly alkaline (pH 7·7) until about the tenth day. I have made use of the method when children were not progressing on ordinary cows' milk mixture, and it appears to me to be a valuable addition to our methods of feeding. It is, however, somewhat difficult to order decinormal hydrochloric acid for out-patients, although the dilute hydrochloric acid of the British Pharmacopœia is decinormal acid, and I am now trying in some cases the effect of using citric acid to neutralise some of the buffer. Citric acid is easier to obtain than decinormal hydrochloric acid. The amount of citric acid which has to be added to cows' milk to bring it to the buffer value of breast milk is half a grain to the ounce of milk. Marriott and Davidson [28] state that citric acid produces diarrhœa, but in the amounts I use I have not found this to be the case. They also object to hydrochloric acid, that this acid is not destroyed in the body, and must be eliminated, thus throwing rather a severe strain on the acid-base regulating mechanism, which may lead to acidosis. This objection receives considerable support from the work of Shohl and Sato.[36] The clinical fact remains, however, that, using hydrochloric acid in the amounts stated above, gains occur and the children do well. In one case, in which the chlorides were estimated in the urine, the amount excreted was not more than the average of 10 atrophic cases fed by other methods. This case also showed a very high percentage of absorption of fat.

The estimation of rennin has been carried out in most of these cases; the method used has been that devised by Miller and Wilcox.[30] I have, however, come to the conclusion that this method does not furnish accurate results in fractional test-meal methods. There are two sources of error, first in the earlier readings the pH value of the stomach contents may not be low enough to activate the rennin, and secondly in cases where there is hyperacidity, as in pyloric stenosis or some cases of pylorospasm, the acid itself may be responsible for coagulating the milk. The controversy as to the identity or non-identity of rennin with pepsin still continues, but the evidence appears to me greatly to favour the view that they are two distinct enzymes. The only group of cases in which the fractional test-meal method gives anything like a real diagnostic help is in pyloric stenosis, in which case there is usually milk-clot and mucin present in the resting juice, often in considerable quantity, and the resting juice shows high total and high free acidity. The emptying time is prolonged occasionally up to five hours; bile has never been found, but there is frequently a considerable excess of mucin, usually high free and total acidity, and there is absence of duodenal regurgitation as shown by estimation of total and mineral chlorides by Volhard's method.

GENERAL METABOLISM IN ATROPHY.

If it be true that, in general, digestion and absorption of food is normal in infantile atrophy, we must look for an explanation of the disorder in the internal metabolism of the body. I regret that I have few observations of my own to submit in proof of the occurrence of a disorder of metabolism. The cases showing a negative and a low calcium balance are, however, evidence in support of this view. This theory receives strong support from the observations of Utheim[8] who found a negative nitrogen balance in 7 out of 18 athreptic infants. Nitrogen absorption was normal, and the negative balance could therefore only be due either to a deficient utilisation of nitrogen or to actual destruction of the body tissues. She found in the urine certain organic acids excreted in excess of the normal, and these acids she regards as products of intermediate metabolism which would normally have broken down in the body. Corresponding with the negative nitrogen balance there was usually a negative or low salt balance. She also repeated and confirmed Freund's observations, that when benzol is given by the mouth to athreptic children less phenol is excreted in the urine than when given to normal children. The conversion of benzol to phenol is an oxidation process, and the differences in the amounts excreted between atrophic and normal children are not due to differences in the absorption from the alimentary tract.

A negative salt balance has also been found by earlier workers, but the strongest evidence in favour of this conception of atrophy is, I think, the work done by two independent investigators, Fleming[16] and Talbot,[31] on metabolism in infantile atrophy. The first of these investigators showed that the greater the degree of wasting the higher the heat output (obtained by indirect calorimetry) per kg. of body-weight—or, in other words, that the basal metabolism of wasted infants is higher than normal infants, and the greater the degree of wasting the higher the basal metabolism. If, however, the heat output per kg. of expected body-weight be considered, it is found that when the wasting has reached a certain degree (a loss of 35 per cent. of the expected body-weight) the greater the emaciation the lower is the heat output. Fleming thinks that it is justifiable to assume from these results that the early loss of weight is due to wastage of fats (or other metabolically inactive tissue), but that when 35 per cent. of the weight has been lost, wasting of the muscular or active metabolic tissues, on which the heat output depends, occurs, and hence the caloric output per kg. of expected weight decreases. There thus appears to be definite evidence of inefficient metabolism, to use his own words, "in atrophy the metabolism is carried on less economically than in health." The results obtained by estimation of the respiratory quotient showed that the tissues of atrophic children were well able to utilise both fats and carbohydrates. Fleming also accepts the view that there is not any evidence of faulty protein metabolism, but I have already quoted what appears to be very reliable evidence to the contrary.

Talbot's investigations confirm and extend Fleming's observations, for he finds that the metabolism becomes abnormal when the infant is 20 per cent. or more below the average weight. Further, he thinks his results show that in atrophy a heat production greater than the normal is necessary to maintain body temperature, because of the relatively increased amount of body surface and the absence of a protective (Lusk) or insulating (Fleming) covering of subcutaneous fat; also, that it is reasonable to conclude that as long as the body is able it will respond to the demand and produce extra heat, but that if the indigestion, which in his opinion is primarily responsible for the malnutrition is not cured, the heat loss eventually will exceed production and a subnormal temperature result. The occurrence of a subnormal temperature, the abnormal sensitiveness of atrophic children to cold, and the necessity of supplying them with artificial warmth are familiar clinical facts.

Clinical verification of the experimental finding that the basal metabolism per kg. of body-weight is higher in infants with severe malnutrition than in normal infants can be obtained by working out the caloric intake of atrophic infants who are improving under treatment. In a considerable number of cases I have worked out the number of calories which have had to be given daily to secure a satisfactory increase in body-weight; I have only on rare occasions based a diet on what I calculated to be caloric requirements. In an unselected series of 40 cases I found that the number of calories per pound of body-weight required is 68, or 149 per kg. of body-weight, the range of calories in the series being 58 per pound (127 per kg.) to 85 per pound (178 per kg.). The highest caloric value diet that I have given has worked out at 108 per pound (237 per kg.) of body-weight, on which the infant did well.

Statements concerning the number of calories required by the normal child in the first few months of life vary according to the authority consulted. Marfan[32] gives 38·6 calories per pound (85 per kg.), which is very far below the figure I have given for atrophic cases. John Thomson[33] quotes Dennett's figures—viz., 50–55 calories per pound (110–121 calories per kg.) for average infants under 4 months and moderately thin infants of any age, and 40–45 per pound (88–99 per kg.) for fat infants over 4 months. According to Morse and Talbot,[34] the normal infant has a basal metabolism of 23–30 calories per pound (50–65 per kg.), and this may be increased from 40 per cent. (i.e., 32 calories) to 100 per cent. (i.e., 46–60 calories per pound) in the change from complete muscular repose to active exercise.

The usual method of feeding in this country has been to feed by weight, for instance, to give to a child 5 months old, having the weight of a normal child of two months, the diet for a child 2 months old. The results of estimating the caloric value of the diets necessary to gain weight, however, shows that the rule should be rather to feed by age—i.e., by expected weight, than to feed by weight. The same end is obtained by certain French pædiatrists—e.g., Variot—who feeds by length and not by weight, and also by von Pirquet's "nem" system. A "nem" is the food value of 1 g. of standard breast milk, and to arrive at the number of "nem" required by an infant the following formulæ are used. At birth 0·5si^2, from the second to the sixth month 0·6si^2, and at the seventh month 0·7si^2, where "si" is the sitting height of the child in centimetres.

Although high caloric feeding appears to be essential to success in treatment, many children, when first coming under observation, are unwilling to take enough food to make high caloric feeding possible. It is a common experience to find that for some time after treatment has been started atrophic children do not show an increase in weight, and, indeed, they may even lose weight. These occurrences may be due to a diet of too low a caloric value, for the reason just mentioned; or they may be due to the possibility that this time represents the "period of repair" to which Marriott refers and during which period, he considers, that there is an effort on the part of the organism to restore the blood volume to normal.

In cases that recover, the recovery is complete and there are no after-effects. A number of cases have recently been examined after an interval of one or two years since their discharge from hospital. These children appear to be normal in every way, except that a few show clinical evidence of mild rickets. In a few cases also on X ray examination there was radiographic evidence of rickets. The only case of severe rickets occurred in a case of pyloric stenosis which had been cured by operation.

After this consideration of the views put forward by workers on this subject, the evidence on which these views are founded and my own results, I would submit that it has been demonstrated that infantile atrophy is not a gastro-intestinal disorder, but that in the present state of our knowledge it should be regarded as a disorder of metabolism, and also that there is a great deal of evidence in favour of the view originally put forward by early English writers on this subject, and now strongly held by Marriott, that the condition is essentially due to starvation. The marasmic condition of infants with pyloric stenosis is obviously due to partial starvation, and all the observations that have been made on their metabolism after Rammstedt's operation and when fed on small feeds show that it is identical with that of infant atrophy.

SUMMARY.

The theory and facts of infantile atrophy that I have attempted to bring to your notice may be shortly summarised. An infant after thriving normally commences to lose weight for one or more causes, such as:—

1. Insufficient food. Either an insufficient supply or because some condition like pyloric stenosis prevents the child from obtaining a normal supply.
2. Unsuitable food. All artificial foods; deficiency in fat or protein; excess of carbohydrates; excess of fat; absence of vitamins, &c.
3. Diarrhœa and vomiting.
4. The occurrence of some infection—e.g., pyelitis, pneumonia.

The conditions described under the last two headings may be cured when the child comes under observation for atrophy.

5. Hygienic surroundings.
6. Pre-natal influences and constitutional causes.

These factors are very real ones and of great importance.

Weight is lost at the expense of the metabolically inactive tissues and water until the child is 20 per cent. under the expected weight for its age. From this point onwards the child becomes an atrophic infant, and is unable to utilise its food properly. The basal metabolism is increased and continues to increase with increasing emaciation; hence high caloric feeding is essential. Absorption from the intestinal tract, except under certain conditions, such as diarrhœa and some forms of fat, carbohydrate and protein indigestion, is essentially normal. It is difficult rigidly to separate the consideration of the various food factors because of their great degree of interdependence—e.g., fats and calcium, fats and carbohydrates; similarly there is difficulty in separating cases into clearly-cut clinical syndromes of fat, carbohydrate, and protein indigestion. The respiratory quotient shows that fats and carbohydrates can be utilised if absorbed; indeed, there appears to be a real sugar hunger. The limit to the intake of sugar is fermentation and the production of diarrhœa; this is a much more frequent occurrence in artificially fed than in breast-fed babies, due possibly to invasion of the upper parts of the small intestine with *B. coli*. When diarrhœa occurs carbohydrate is not absorbed well and weight is lost. In the absence of diarrhœa, therefore, considerable quantities of carbohydrates can be absorbed, and to obtain this end—i.e., freedom from diarrhœa—a less fermentable sugar, such as dextrimaltose, is used.

Many of these children can and do absorb a larger amount of fat per kg. of body-weight than normal children usually do, but a high fat dietary may cause fat indigestion, and in diarrhœa, however produced, there is diminished fat absorption. Calcium absorption is usually very good if a sufficient supply of fat and calcium is present in the food; indeed, many absorb more calcium per kg. of body-weight than normal children usually do; but in a poor fat or calcium dietary the absorption is not good. There is, however, in many cases faulty salt metabolism, which may result in low retention values for calcium. Protein metabolism is also faulty. The absorption of protein is normal: protein indigestion is a rare condition and has only been seen where there has been a large protein intake over a considerable period. The metabolic disturbance is essentially an abnormal salt and protein metabolism, resulting in poor retention values for mineral salts and nitrogen.

THE RAPID CONTROL OF DIPHTHERIA OUTBREAKS IN INSTITUTIONS.

BY C. C. OKELL, *M.C.*, M.B., B.CH. CAMB.;

A. J. EAGLETON, M.D. LOND.;

AND

R. A. O'BRIEN, C.B.E., M.D. MELB., D.P.H.

(*From the Wellcome Physiological Research Laboratories.*)

IT would appear at first sight that testing by the Schick method and active immunisation against diphtheria can be usefully employed only during the inter-epidemic periods, but are of little value in dealing with an active epidemic. These newer methods of prophylaxis are, however, of great value in the control of epidemics, at least in camps, schools, hospitals, or similar institutions where the population is under control. The customary method of handling such epidemics is to swab the throats and perhaps the noses of all the subjects and to give antitoxin to those who have been in contact with "cases" or with known carriers; it is, however, difficult to know how close has been the contact between given individuals.

It is important to remember that, from the point of view of their immunity and infectiousness, six types of subject may be met with. We may divide a population into two groups, "Schick positive reactors" and "Schick negative reactors." We may further divide each group into those with "negative" swabs and those with "positive" swabs, the latter being again divided into those yielding virulent and those with avirulent diphtheria bacilli. These six types may be set out thus:—

A. Schick positive, swab negative.
B. ,, ,, ,, positive, bacilli avirulent.
C. ,, ,, ,, ,, ,, virulent.
D. ,, negative ,, negative.
E. ,, ,, ,, positive, bacilli avirulent.
F. ,, ,, ,, ,, ,, virulent.

The usual method of dealing with a population infected with diphtheria depends upon the bacteriological findings alone, those with "negative swabs" remaining free, while those yielding "positive swabs" are isolated. The isolation ward would then contain classes B, C, E, F. Class C are obviously those incubating diphtheria, and such subjects will, within a day or two, develop clinical diphtheria. These are rightly present in the isolation ward. Class E are not susceptible to diphtheria and are of no further interest; since their bacilli are avirulent it matters not whether people in this class are free or isolated. But the juxtaposition of F, the non-susceptible carriers of virulent bacilli, and B, the susceptible subjects, involves danger. If amongst F there exist "profuse carriers" the danger to class B is acute.

We recently had occasion to examine a small ward in which were isolated patients whose swabs had previously been diagnosed "positive." We found, amongst nine patients, representatives of classes B, E, and F. A smear made from an overnight culture of one of the patients resembled that from a clinical case of diphtheria, showing practically nothing but bacilli morphologically resembling Klebs-Löffler bacilli; the bacilli proved virulent. The girl gave a "negative response" to the Schick test. She clearly belonged to class F and was a "profuse virulent carrier," and, one must assume, a source of acute danger to people in class B, who are susceptible to diphtheria.

It may be objected that all in the isolation ward would receive protection from an injection of diphtheria antitoxin. The disadvantage of this procedure is that the protection rapidly disappears, and in a few weeks the susceptible people are again exposed to danger. We have had under observation during the past year and a half an institution in which prophylactic injections of antitoxin were given to all the inmates. The epidemic at once ceased, but about a month later cases of diphtheria began to recur; injections were again given, but sporadic cases occurred for many months. Our advice was then asked. Since the children were all very young and one might get Schick negative reactions due only to passive immunity derived from the mother, we urged active immunisation with toxin-antitoxin mixtures. This has been done and the children are now immune.

Precautions against Danger of Mixing Virulent Carriers and Susceptible Patients.

In order to avoid the danger of mixing classes F and B, the "virulent carrier" and the susceptible patient, we would recommend, as the result of our experience in a recent hospital epidemic, the following procedure. When an outbreak has occurred, test every inmate at once by the Schick method and swab throat and nose. Within 24 hours the results of the Schick test can be read with 90 or 95 per cent. accuracy (and a day or two later with practically 100 per cent. accuracy). The results obtained from the Löffler culture made from the swab are also known within 24 hours. The object of the common procedure of swabbing is to detect the dangerous "carrier." We can, however, do this by the use of the Schick test alone with fair certainty, by isolating at once all those in classes E and F, while those "Schick positive" and "swab positive" can, with little danger, remain free but subject to inspection twice daily for a day or two. At this inspection any person incubating diphtheria (in the rare instances where a representative of class C is present) is detected at the earliest onset of illness with sore-throat, and is given antitoxin immediately. Within two to seven days the results of the "virulence test" of cultures from classes E and F will be known and E may be released. There will remain group F, the dangerous carriers. The further treatment of these people is a problem of administrative difficulty and can apparently be met only by isolation until a succession of "negative swabs" can be obtained. In a group of 11 boys we have recently examined, eight yielded successive negative swabs after an average of four weeks' isolation. It is necessary to relieve pathological conditions of nose and throat and remove tonsils if the infection persists in them. Obstinately persistent virulent carriers are met with occasionally; the community has not yet discovered what is to be done with such people, but at all events they will, by the procedure above described, be removed from their companions in the institution.

Rapid Establishment of Control.

The method outlined above calls for a moderate amount of immediate work, which is well repaid by the rapid attainment of control. One may, if necessary, reduce the immediate work by postponing the swabbing. The Schick test can, if discipline and organisation are good, be done rapidly; we recently found that a pair of operators could do the intracutaneous injections for 286 patients in 68 minutes. The Schick test results will enable one next day to isolate all Schick negative subjects; these can be swabbed as soon as time permits and those with a "negative swab" released, while cultures from the "positive swab" patients are tested for virulence. Those with avirulent bacilli are at once released and the dangerous F group retained.

With regard to the Schick positive "reactors" if they are to remain in the institution for many weeks one proceeds at once to immunise them. It has been our experience during the past year that three injections of toxin-antitoxin mixture given at weekly intervals cause from 50 to 80 per cent. of the people to become Schick negative reactors within two weeks of the last injection, and upwards of 80 or 90 per cent. within four or six weeks of the last injection.

Basis of Effective Control.

It will be seen that the plan advocated here depends upon the truth of the following "propositions": (1) Schick negative reactors are not susceptible to diphtheria. (2) Schick positive reactors are susceptible to diphtheria. (3) Schick positive reactors never harbour virulent bacilli detectable by ordinary swab-culture methods unless they are suffering from or are incubating diphtheria. (4) Carriers of virulent bacilli are immune and are always negative Schick reactors. (5) "Avirulent" bacilli do not cause diphtheria, and therefore "avirulent carriers" are of no importance to the public health authority. (6) One efficient swabbing of a population gives a sufficient working knowledge of the location of infection—i.e., all "profuse," and therefore dangerous, carriers will be detected.

We are fully aware that the truth of these "propositions" may be contested. It is, however, sufficient for effective control if they approximate to truth, and we think the available experience of other workers and our own results indicate that these propositions represent a very close approximation to truth. We would maintain with confidence that by the application of the measures suggested one can, within 24 hours, obtain effective control of an outbreak of diphtheria in any institution where efficient isolation can be ensured. We hope the method will be thoroughly tested.

Summary.

In an outbreak of diphtheria:—

1. Schick test all patients.
2. If possible swab all patients, throat and nose.
3. Next day, isolate in one ward all "Schick negative" patients.
4. For a few days, see twice daily all "Schick positive" reactors.
5. Test for virulence all positive swabs from "Schick negative" reactors; release "avirulent" but rigidly isolate all "virulent carriers."
6. Commence at once to inject toxin-antitoxin mixtures into all "Schick positive reactors."

Note.—Since writing this paper our attention has been called to the valuable study by E. H. R. Harries on the Carrier of Diphtheria Bacilli from the Fever Hospital Standpoint in the *Medical Officer*, March 4th, 1922, where a similar method was suggested. "On the occurrence of clinical diphtheria in a scarlet fever ward, it is not a difficult matter to Schick test the remainder of the ward, and so separate the susceptible from the non-susceptible cases. Susceptible cases can be placed apart and if necessary be passively immunised by antitoxin." We hope that Dr. Harries will soon publish his further experience with the method.

Clinical and Laboratory Notes.

TEMPORARY COLOUR-BLINDNESS.

BY F. W. EDRIDGE-GREEN, C.B.E., M.D. DURH.,
F.R.C.S. ENG.,
SPECIAL EXAMINER AND ADVISER TO THE BOARD OF TRADE ON
COLOUR-VISION AND EYESIGHT.

THOUGH congenital colour-blindness has chiefly occupied the attention of those who have paid attention to the subject, it is well known that colour-blindness may be acquired through disease or injury. These cases have been regarded as permanent. It is, however, not known that colour-blindness similar in character to a very bad dichromic may occur as a purely temporary condition.

The colour sense, even with normal-sighted persons, varies according to the condition of the health. When a series of colour equations have been made by three normal-sighted persons it will be found that on certain days one of the three will put more or less green in the equation than on the previous occasion, whilst the other two observers will make the same equation as before. This condition, whilst a disturbing factor, usually varies within the limits of normal colour-vision. The nerve cells whose function it is to perceive colour seem to be much more liable to affection by disease, especially by toxic influences, than those of the visual centre. Acquired colour-blindness seems to be closely related in its general characters to the congenital form. A man suffering from general paralysis of the insane may pass through all the degrees of congenital colour-blindness. A woman became totally colour-blind after ear disease; she was examined when she was regaining a certain amount of colour perception and could distinguish between red and violet, the rest of the spectrum appearing grey. A signalman became totally colour-blind after tetanus, his visual acuity being partly 6/6; he had previously passed the wool test several times.

The following is an illustrative case. The examinee was a man who had just recovered from influenza, but he appeared perfectly well and made no complaint of any kind. His form vision was 5/5 partly, both eyes being used. Examined with the lantern he called green both white and red; red he called white, and white red.

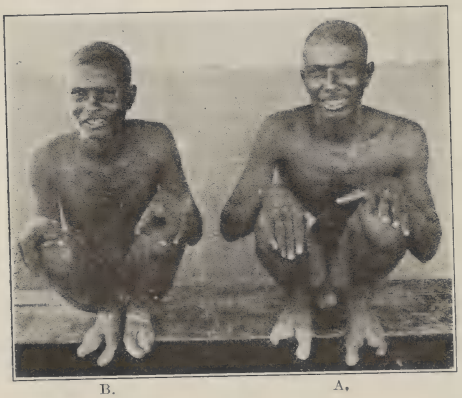
Examined with the spectrum he called the region from λ 650μμ–λ 571μμ (red, orange, yellow, and yellow-green) red; the region from λ 571μμ to λ 538μμ (green) white; the region from λ 538μμ to λ 442μμ (green, blue, and violet) blue; and purple from λ 442μμ to the end. The apex of his luminosity curve was at the normal point λ 585μμ. He made the following equations: 45 red λ 665μμ mixed with 2 of green λ 520μμ matched 15 white. The normal equation is 45 red with 13 green equals 16 white, so that he was matching a bright red with white. He made an equation of 10 λ 633μμ red with 6 λ 540μμ green equals 22 white. He also agreed with the normal equation which is 10 red and 10 green equals 20 white, but required the comparison white light increased in luminosity. Examined again five months afterwards his colour-vision was normal in every respect.

TWO CASES OF CONGENITAL DEFORMITIES OF THE HANDS AND FEET.

By NORMAN F. SMITH, M.B., B.CH. OXF.,
MEDICAL INSPECTOR, SUDAN GOVERNMENT.

THE two men depicted in the illustration are brothers from a village near Luxor who passed through quarantine at Wadi Halfa on their way to work on the cotton plantations in the Southern Sudan.

History.—A. is aged 20, B. 18 years. There are two elder sisters and two younger sisters and one younger brother. No other members of the family are known to suffer from any deformity. The condition is attributed by the natives to the fact that during these two pregnancies their mother developed a craving to behold geese, which she apparently satisfied to the full. They call the condition "goose-foot."



Sudanese brothers, aged 18 and 20 years, with congenital deformities of hands and feet.

Present Condition.—Both men, with the exception of their fingers and toes, are well developed and of normal intelligence, showing no signs of disease. My own camera being out of action, I sent for the local native photographer; unfortunately the "close-up" photograph of the hands were failures. Also I had no X rays at my disposal.

The detailed description of the conditions is as follows:—

CASE A.—Left hand: normal.

Right hand: Thumb webbed and stunted, hand otherwise normal.

Left foot: "Cloven." Big toe normal; second and third toes not represented beyond metatarsals. A median cleft runs proximally the whole thickness of the foot to the fibular side of the ball of the big toe. Fourth toe not represented. No metatarsal. Fifth toe acutely flexed. Otherwise normal.

Right foot: "Cloven." Big toe normal; second and third toes not represented beyond metatarsals. Fourth and fifth toes syndactyly. Two nails.

CASE B.—Left hand: Thumb diminutive, otherwise normal. Index finger, two sets of phalanges, (*a*) diminutive and springing from first metacarpal, (*b*) normal in size, but bent by webbing to meet (*a*) at base of one large nail. Middle finger represented by a soft pad over head of third metacarpal bone from which runs obliquely a phalangeal bone to join the first interphalangeal joint of the ring finger. Ring finger normal. Little finger normal.

Right hand: Thumb and index finger syndactyly. The first and second metacarpals run side by side. The two second phalanges are fused into a triangular plate bearing two equal nails. There is no joint between the first phalanges and this plate. Middle finger completely flexed by webbing. No sign of nail formation. Ring finger normal. Little finger normal.

Left foot: "Cloven." Big toe valgus, otherwise normal. Second and third toes not represented; no metatarsals; cleft as in A. Fourth and fifth toes, complete syndactyly. Two well-formed nails.

Right foot: "Cloven." Big toe normal. Second and third toes not represented; no metatarsals. Fourth toe, metatarsal fused with fifth, a diminutive toe.

The points of especial interest would seem to be: (1) The variety of deformities found in each case; (2) the entire lack of symmetry; (3) the absence of family history; (4) the comparative rarity of survival to adult life of persons suffering from congenital deformities amongst semi-civilised peoples; (5) the attributed "exciting cause."

RHINOSPORIDIUM SEEBERI (KINEALYI) IN A MALABAR WOMAN.

BY T. S. TIRUMURTI, M.B., C.M. MADRAS,
L.T.M. & H. LOND.,
MADRAS MEDICAL SERVICE.

IN a paper on *Rhinosporidium Kinealyi*, by Major R. E. Wright and myself, read at the Indian Science Congress held at Madras in January, 1922, it was pointed out that no case of infection of woman by the parasite had been observed by us or recorded in the literature. It was our opinion that women were susceptible to infection and that such cases were being missed or overlooked. In October, 1922, Major G. Pandalai, I.M.S., consulted me about a Malabar woman who had a recurring nasal polypus, and I am indebted to him for the following history of the disease in this patient. The history is interesting also for the facts that the nasal growth had recurred for the eighth time and that the disease lasted for nearly 20 years.

The case is that of a married woman, aged 34, with healthy children, who have no nasal polypi. She began 20 years ago to have nasal obstruction. There is deformity of the bridge of the nose. The nasal polypus was removed by forceps for the first time in 1904, and the recurring growths subsequently in 1908, 1910, 1914, and 1916. In 1918 the growth reappeared and was taken out by forceps; the base of the growth was cauterised and part of the middle turbinal removed. The growth, however, recurred and was removed in 1921 by forceps. On none of these occasions was the growth sent up for microscopical examination. In October, 1922, the polypus was observed to reappear in the nose and Major Pandalai snipped off a piece for microscopical examination which confirmed its rhinosporidial character. At my suggestion a 2 per cent. watery solution of tartar emetic locally is being tried. I heard that the patient had some relief in the nasal obstruction. A cure by tartar emetic local application is not claimed, as the patient is still under observation.

I am confident that, if a systematic microscopical examination of all nasal polypi removed by operation at the various hospitals in the Madras Presidency were conducted, many cases of the parasitic infection in women would be brought to light.

ROYAL SOCIETY OF MEDICINE.

SECTION OF NEUROLOGY.

The Value of X Rays in Cerebral and Spinal Localisation.

A meeting of this section was held on April 10th, Dr. Wilfred Harris being in the chair, when the discussion took place on the value of X rays in the localisation of cerebral and spinal tumours, with special reference to ventriculography and lipiodol injections.

Mr. **Percy Sargent**, in opening the debate, said that last year he saw Prof. J. Sicard at work in Paris on cases in which radiography was carried out after the injection into the spinal theca of a substance which was opaque to X rays. He was greatly impressed by the possibilities of the method, and had used it on a number of occasions. The substance was an oily preparation obtained from the seeds of the black poppy and was impregnated with 40 per cent. iodine. That no ill-results had been recorded from its use was probably attributable to the extreme slowness with which the iodine was absorbed; indeed it was not known how long the lipiodol would remain in the tissues, but it was certainly longer than three months. The injection was done with the patient seated in a wheel-chair, and as soon as it was finished he was wheeled to the X ray room. The head of the patient was slightly inclined forwards, and an ordinary lumbar puncture needle introduced into the mid-line between the atlas and the occipital bone. When the atlanto-occipital ligament had been pierced, there was a 1 cm. space before the cord was encountered, therefore careful manipulation should prevent the cord being wounded. An empty needle was inserted, and a little cerebro-spinal fluid withdrawn, and then 1 to 2 c.cm. of lipiodol injected, and, with a second syringe, a few c.cm. of normal saline, the latter for the prevention of staining of the tissues on withdrawal of the needle. By the time the patient reached the X ray room the lipiodol had fallen to the bottom of the theca, where it was usually seen as a cone-shaped or a rounded mass if no block existed. Where a complete block was present, the lipiodol was arrested at that point. He showed a skiagram of a case of extra-thecal sarcoma, in which symptoms had existed about ten weeks. The signs of pressure were severe, but not complete, and the actual level varied somewhat and was not very clearly cut. Injection of lipiodol into the theca showed the exact situation of the upper limit of the block, and this was verified at operation. Another case portrayed was that of a neuro-fibroma situated on one of the roots inside the spinal theca; the neurological signs corresponded. At operation he found that the curved line in the skiagram represented the upper surface of the tumour, and the method not only confirmed the neurologist's opinion, but showed that the tumour could be removed through a comparatively small opening, nothing in the way of exploration being required. To determine upper and lower limits of the block two injections should be done, one with the patient tied to the table and inverted on it.

As extra-medullary tumours were usually small, and intra-medullary tumours might extend over many segments of the cord, this technique possibly presented a help towards the differentiation of intra-medullary from extra-medullary tumours. He had also used the method satisfactorily in a case of meningitis circumscripta, of which the skiagrams were exhibited. He had also found the method valuable in cases in which the neurological signs as to the upper limit of the lesion were variable or equivocal. One instructive case was that of a man, aged 38, who for more than two years had had a fixed pain at the level of the ninth thoracic root, with disturbances of micturition, weakness of legs, and defective sensibility of certain segments. The symptoms varied not only from day to day, but almost hourly. Injections of lipiodol on three occasions, the second at 54 hours and the third at 120 hours, determined the site, and laminectomy revealed a condition in which there were large angiomatous vessels, giving an appearance similar to cirsoid aneurysm, this providing the key to the variability of the symptoms. Mr. Sargent had also used it in two cases of spinal caries with a partial compression paraplegia, and each showed a long persistent streak of lipiodol along one aspect of the cord. As neither had yet been operated upon, he was unable to give any explanation of the appearance. Summarising, he said that in this method the profession possessed an aid to diagnosis which was of considerable value. It enabled one to ascertain whether or not there was a block in the spinal theca, and to know whether a block was complete or only partial; and in the latter one derived a good indication for operative attack. By it, also, one could distinguish between meningitis and other conditions, and between intra- and extra-medullary tumours. In addition, it gave evidence of the exact relations of the tumour to the bones, and enabled the surgeon to approach the lesion with greater precision and through a smaller wound than formerly.

Mr. **Geoffrey Jefferson** devoted his attention to the radiographic diagnosis of pathological conditions within the skull, and particularly to the localisation of cerebral tumours, and the advantages which seemed to accrue from the injection of air itself. He first showed skiagrams of skulls of cases which during life had sustained great increase in intracranial tension; in some there was a curious sand-rippling appearance in the frontal region, and the pituitary body was compressed. In a case of hydrocephalus the diaphragma cellæ was widely opened. In some similar cases there were a number of small herniations and a disappearance of the posterior clinoid processes. He advocated the routine taking of stereoscopic skiagrams, and keeping a watch for all possible points of bone erosion, especially round about the middle fossa and the lesser wings of the sphenoid. One might then gain valuable information in the localisation of basal endotheliomata, as these caused proliferation of overlying bone. Speaking of ventriculography, he said it was, especially in this country, still very much in the balance. It was largely accepted, and was being used increasingly in the United States. The chief trouble was that which followed on its advocates having claimed more for the method than the cases seemed to justify. The speaker had made 13 air injections on ten patients, and as a result he felt more favourably disposed to the method than he was at first. If the appropriate diaphragm was used, good results should be obtainable with small quantities of air injected and the invariable use of stereoscopic skiagraphy. No doubt ventriculography had a definite mortality; two of his own ten cases had died. One was a child with hydrocephalus, and it died three days after replacement of 80 c.cm. of cerebro-spinal fluid by air. Possibly the child might have died after a puncture of any kind, but the death should be attributed to the particular procedure. In the other fatal case he had tried bilateral occipital puncture in a case in which a cerebral tumour could not be localised, and he failed to strike the fluid with either of his tappings, and the woman died a week later. No post-mortem was allowed. He entertained considerable hopes from the method following upon experience and improved technique, for several points had not yet been settled. One concerned the amount of air which should be injected. Should one be satisfied with extracting 20 to 30 c.cm. of cerebro-spinal fluid? He had been disappointed by the results when using only 25 c.cm. of air.

Discussion.

Sir **James Purves Stewart** said he considered that the injection of air into the spinal theca was of diagnostic value, and he showed a number of skiagrams of cases in which he had carried it out. It was especially useful in regions where diagnosis with exactitude was notoriously difficult. In some cases he got a definite picture from the injection of 70 c.cm. of air 5 c.cm. at a time. Precision was greatly helped by this method in supra-tentorial tumours. He also showed a number of X ray plates derived after injection of lipiodol, and remarked on the importance of having the patient's head in the right position when carrying out the injection.

Mr. A. A. McCONNELL also showed a number of skiagrams of his cases in which he had injected lipiodol. One was that in which it could not be determined whether the patient had a frontal tumour or a posterior fossa tumour. An X ray diagnosis was made following ventriculography, and after death a glioma of the frontal lobe was found, which bulged into the anterior horn. Two of the ten patients on whom he did the successful introduction of air died, one eight hours after the injection, the other 14 hours after, and both died in the same way—i.e., suddenly, as if they had been shot. Both had posterior fossa tumours and gross deformity of the medulla. It was questionable whether those fatalities were definitely due to the air injection, as sudden death was not uncommon in such cases; still, it was safer to blame the method, and study how they could be avoided in the future. He regarded as the most important item in the technique the avoidance of any sudden change in the intracranial pressure from the injection of air, and that could be ensured by the slow withdrawal of only small quantities of fluid at a time, not more than 5 c.cm., the blood pressure being taken as the criterion of the intracranial pressure. In cases of internal hydrocephalus the occipital route was the easiest by which to reach the ventricle, but when the ventricle was small or normal the lateral method was best. Injection into the lumbar region gave him less information than direct injection into the ventricle did. The injection of 25 c.cm. of air should cause the condition to show up well. He referred to the fact that there was still a good deal of uncertainty in the interpretation of radiograms, even of the stomach, and considered that a careful use and study of this method would result in deriving much help from it.

The CHAIRMAN said that ventriculography seemed to him to be a dangerous procedure, and that it should not be done unless grave reason could be shown for it. The use of lipiodol in the way described seemed to be much less dangerous, and the advantages appeared so obvious from Mr. Sargent's slides that it was probably a justifiable procedure.

Mr. L. B. RAWLING said he felt that lipiodol was a substance which should be tried; it appeared to be devoid of danger, and in some cases gave quite good results. He shared Dr. Wilfred Harris's views on ventriculography; it did not promise much advantage, and seemed to present considerable risks.

Dr. C. P. SYMONDS said that the absence of a high protein content in the cerebro-spinal fluid obtained from lumbar puncture did not absolutely exclude the presence of a compression lesion of the spinal cord. A recent case he had was that of woman who for some time had a transverse lesion of the spinal cord. She had been under his care before, when the fluid from lumbar puncture had a normal protein content. On this later occasion it contained 0·2 per cent. protein, and on injecting lipiodol it was completely arrested at the fourth dorsal level. Operation was done and an extra-dural lipoma was removed. An interesting point was as to which method of inquiry was likely to give the first evidence of subarachnoid blockings, lipiodol injections or estimations of the protein content of the cerebro-spinal fluid.

A number of questions were asked, and the openers briefly replied.

SECTION OF ORTHOPÆDIC SURGERY.

DISCUSSION ON TUBERCULOUS DISEASE OF THE HIP-JOINT.

A MEETING of this section was held on April 1st, with Mr. R. C. ELMSLIE, the President, in the chair, when a discussion was held upon the Treatment and Functional Results of Tuberculous Disease of the Hip-joint.

Urgency of Early Treatment.

Mr. W. T. G. PUGH, who opened the discussion, said that it was now almost unnecessary to emphasise the extreme importance of heliotherapy (or artificial light treatment during the winter months), for the great value of this form of treatment was now widely recognised. Yet the urgency of the need for early treatment in the country of tuberculosis of bones and joints had not yet been fully impressed upon the profession, and the earlier diagnosis which undoubtedly obtained now was not always followed by early treatment upon the best possible lines. Less than one-fifth of the cases admitted to Carshalton came during the first three months of the disease. According to accepted pathology, the tuberculous process began in the red marrow of the head of the femur and was for a variable time confined to the bone. Though certain sympathetic changes took place in the joint during this stage these were capable of complete resolution. If, however, the tuberculous focus were allowed to find a way into the joint, as it generally did within three months, permanent damage to the joint was inevitable. Cases were cited and photographs exhibited to illustrate the almost perfect functional results with a mobile joint which had been obtained when the correct treatment was instituted during the first stage; these were contrasted with the results of treatment begun after this stage had passed. A possible objection that there was no definite proof that the first series of cases was truly tuberculous could only be met by the reply that such happy results could only be obtained when the treatment was instituted at such an early stage that the diagnosis rested upon the symptoms and the interpretation of the X ray plate; the classical signs described in text-books were those of the later stage in which the joint was grossly infected.

Deformities Resulting from Incorrect Treatment.

Genu recurvatum was a deformity not uncommonly seen in cases which had been recumbent for a year or more with the knee fully extended. Where prolonged recumbency was necessary the knee should be kept slightly flexed. Genu valgum occurred generally from faulty splinting, but also at times from no ascertained cause. Scoliosis also was due to faulty splinting together with fixation of the hip in insufficient flexion and resulted from the efforts of the child to twist the body into a "sitting position" with the diseased hip held rigidly in full extension. Where the hip was ankylosed the speaker considered the optimum position to be one of 35° of flexion measured with the lumbar spine in contact with the table. This constituted the most satisfactory compromise; more flexion, while giving greater comfort in sitting down, produced a degree of lordosis in standing which often became painful in later life. For the correction of the lesser degrees of adduction Mr. Pugh practised and advised tenotomy of the adductors; but where the adduction was extreme and there was a fibrous ankylosis of the hip recurrence took place after tenotomy so that he performed a sub-trochanteric osteotomy and allowed the upper end of the lower fragment to unite with the pelvis or the lower part of the femoral neck. As regards the treatment of "abscesses," he preferred simple aspiration and did not inject any solution. When aspiration had failed or a soft spot had formed in the deep fascia he considered further delay useless and operated with the most rigid aseptic precautions, expressing the lining membrane and sewing up the wound. Sinuses were excised; the wound was bipped and sewn up without drainage. This failed in about 40 per cent. of cases, but a repetition of the operation after an interval was usually successful.

Mechanical Methods of Fixation.

Thomas, whose splint was first described 49 years ago, treated his better-class patients with splintage in bed, but his hospital patients were allowed to get about in the hip-splint with crutches and a patten on the sound foot. The latter practice resulted in a hip ankylosed in some adduction. Since the speaker believed that pressure between the joint surfaces had a prejudicial effect, he regarded some form of traction as essential in addition to immobilisation. After describing briefly the methods of fixation employed by Sayre, Lorenz, Sir R. Jones, Rollier, and others, Mr. Pugh proceeded to describe the method employed at Carshalton. With early and adequate treatment useful movement of 20° or more might be obtained in many cases, and this should be the aim of treatment. The deformity should be corrected by steady traction, under an anæsthetic if necessary, and weight extension applied to the thigh by moleskin strapping. If there was much thickening with considerable deformity it was better to correct gradually by weight extension. The joint should at the same time be immobilised by a plaster spica, the front part of which should be removed to allow of the detection of abscess formation. A perineal band for the opposite groin should be attached to studs fixed in the plaster; the latter, while it did not interfere with traction, prevented jarring of the joint and consequent muscular spasm when the bed-pan was given. The use of a frame and carriage as at Carshalton had the advantages that both knees could be kept slightly flexed, rotation could be prevented by the use of a sandal to which a wire support was attached, and exercise of the sound limb became possible without disturbing the affected joint. When the disease was quiescent, as shown by X ray examination and the fact that even slight tonic contraction had been completely absent for months, the weight extension which had been gradually reduced should be omitted, and the movements which the patient usually tried to make at this stage encouraged under careful supervision; no attempt at passive movement, however, should be permitted. The longer this stage was prolonged the greater the mobility was likely to be, but the position of the limb should be carefully observed and the progress of healing checked by X ray examination. When the patient got up he should wear a short celluloid spica or similar splint and be allowed to walk on patten and crutches. When he was in bed the spica need not be worn and he should be allowed to move the joint if any movement was possible. Especially when the joint was fixed it was important that he should be seen every week for a considerable period after the spica had been omitted lest flexion deformity occurred.

Other Methods.

Mr. T. P. McMURRAY (Liverpool) said that after Mr. Pugh's remarks it might be forgotten that the disease was not confined to the young but could occur at any age. This fact must not be overlooked. The diagnosis was usually made easily from the presence of rigidity in every direction, and should be followed by immediate and complete fixation. He employed a frame with fixed extensions in a recumbent position for a period, which varied according to the nature of the case. In the absence of a sinus, fixation lasted from 15 to 24 months. The period of recumbency came to an end when pain had been absent for six months. He considered a frame to be better than plaster as a means of fixation in the early stages since it permitted heliotherapy. Too great a degree of abduction should not be aimed at on account of the scoliosis and pain which might be produced. As regards the operative treatment, he considered that the mortality was so high that operation was never justifiable in uncomplicated cases of this disease which, as Ford remarked in 1792, was rarely fatal, unless a sinus and secondary infection occurred. With regard to abscesses, he found that the progress of many was checked by mere fixation of the joint, and only rarely was he forced to aspirate. In the latter event he usually made injections of one of the many fluids which were recommended, and he considered this exercised a beneficial effect. In the presence of a sinus leading to a detached and carious femoral head he operated and removed the head, but did not interfere with the tuberculous granulation. Other factors in the treatment were open air, and sunlight or artificial light in winter. The end-results that might be obtained were either bony ankylosis from complete destruction of the joint surfaces, or fibrous ankylosis either fixed or permitting a very limited range of movement which was frequently painful. Of these he considered bony ankylosis to be the better result. In his opinion cases which recovered with a complete restoration and perfect functional mobility of the joint had been erroneously diagnosed as tuberculous.

The PRESIDENT considered that it was quite possible to obtain perfect functional mobility in certain cases of tuberculous hip disease, for he had seen such cases recur after an interval and progress in the usual manner. One of Mr. Pugh's cases, however, he regarded as a case of cystic disease of the head of the femur, and in a similar case he, the President, had had a good result from operative treatment. He was quite sure that there was a place for operative treatment in certain cases, and he quoted a case in which excision of the head of the femur 15 years ago and dislocation of the neck on to the dorsum ilii had resulted in a cure with bony ankylosis. The patient was now able to walk 10 or 15 miles. Arthrodesis was not possible, or at least not safe, in the early stages of the disease, but was called for particularly in the later stages in adolescents or adults. It might then give the best possible result.

Sir HENRY GAUVAIN agreed almost entirely with Mr. Pugh as regards the possibility of complete recovery, but thought that there were still a number of unclassified diseases which resembled tubercle (of which Calvé's pseudo-coxalgia was only one) which responded admirably to the ordinary treatment of a tuberculous joint. In the local treatment he found that plaster moulded around the condyles afforded a good purchase for extension while leaving the knee free. If the knee were not allowed this freedom "genu recurvatum" and the condition he called "dimpled" tubercle, in which the patellar tubercle was replaced by a depression, were apt to occur. To ascertain when the patient might be allowed to sit up, he employed rotation of the femur in a jerky manner: so long as this produced spasm spreading to the abdominal muscles, recumbency was necessary. He could show cases which exhibited a complete return of function after having had abscesses in which the tubercle bacillus was demonstrated. Sea-bathing was an admirable adjunct to heliotherapy in quiescent cases.

Mr. H. A. T. FAIRBANK pointed out that if the diagnosis were made early the disease was outside the joint. In these cases, and in cases of synovial disease, it was quite possible to get a movable joint. As regards the need of flexion, he agreed that 35° was an admirable compromise, but thought it safer to aim at less flexion than was really desired, otherwise it might be difficult to prevent ankylosis at a right angle. Adduction would often recur after correction; in obstinate cases he had once or twice performed exsection of the obturator nerve by the extra-peritoneal route. He had X ray pictures which showed the adduction occurring at the epiphyseal line. In his experience true bony ankylosis was a very rare result in this disease.

Mr. ACTON DAVIS had seen a tuberculous hip recover with complete mobility. As he then regarded the case as not tuberculous the usual scheme of treatment was not carried out, and the child reappeared some time later with recurrence of the disease. He emphasised the fact that the functional results of treatment might be very good in cases exhibiting flexion and adduction, which anatomically could only be described as bad.

Mr. P. B. ROTH thought that the hip-joint was the joint which reacted best to heliotherapy. As a test of cure, he preferred a return of the normal density of the head of the bone to the Gauvain spasm test. He agreed with speakers other than Mr. McMurray as regards the treatment of abscesses and the desirability of a small angle of flexion. In his opinion the weight of the limb produced the necessary traction when Thomas's hip splint was used in the upright position.

Mr. MCCRAE AITKEN thought that synovial tubercle often recovered with a movable joint, but such cases were apt to suffer bone infection later. He had now come to the conclusion that some form of arthrodesis was the best form of treatment for old painful fibrous ankylosis or unstable joints with destruction of the head.

Mr. PUGH and Mr. MCMURRAY briefly replied.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on April 3rd, Dr. G. M. DUNCAN, the President, being in the chair, when Dr. G. MATTHEW FYFE read a paper on the

Treatment of Gonorrhœa in the Male.

After a brief sketch of the history of the disease and the anatomy of the parts, Dr. Fyfe pointed out that it was only to-day that organised scientific effort was being made to combat the evil, and went on to discuss the subject under three heads: (1) the abortive treatment of gonorrhœa; (2) the treatment of acute, subacute, and chronic gonorrhœa; (3) the standard of cure. The abortive treatment might be early or late, according as it was applied immediately after exposure, when the organism might or might not be present, or during the period of incubation, or applied when the disease had just become manifest. If the patient asked for advice after having run the risk of infection, but without showing any definite symptom, an attempt was first made to arrive at a diagnosis by microscopic examination of scrapings from the navicular fossa, and the urine was examined to exclude the possibility of recurrence of an old infection. Twice daily irrigation for three days was then instituted with two pints of a 1/8000 alkaline solution of potassium permanganate. The parts were anointed with calomel ointment, the penis strapped up, and an alkaline diuretic mixture given. If the patient presented himself with a discharge of not longer than 24 hours duration, after a proper diagnosis one of two treatments was used: either irrigation with two pints of 1/4000 alkaline potassium permanganate solution and the immediate injection of 10 per cent. argyrol or lunosol twice daily for four days, and then irrigation alone for another four days; or the sealing into the anterior urethra of 5 per cent argyrol or 10 per cent. lunosol for six hours daily for five consecutive days. Both these methods were found eminently successful, but Dr. Fyfe pointed out that the eligible patients were few.

For the treatment of acute gonorrhœa Dr. Fyfe emphasised the necessity of a careful diagnosis between anterior and posterior urethritis. Instrumental interference for diagnosis was not recommended in acute cases, as the simple two-glass test was found sufficiently reliable; palpation of the prostate should be a routine. Every effort should be made to prevent an anterior urethritis from extending posteriorly. The general treatment of acute gonorrhœa, which was highly important, consisted in confining the patient, if possible, to bed, on a bland diet with copious draughts of water, alcohol in any form being strictly forbidden, rest, hot hip baths, suspension of the parts by a T-bandage, regular evacuation of the bowels, and large doses of an alkaline diuretic with hyoscyamus and buchu. The local treatment consisted in anterior irrigation, preferably by means of a can and nozzle. The findings at the Aberdeen Clinic were in favour of anterior irrigation solely, the most useful fluid being a solution of potassium permanganate rendered alkaline by the addition of sodium carbonate, commencing with a dilution of 1/8000 gradually increased to 1/4000. If the subacute stage became prolonged, a change might be made to zinc sulphocarbolate, 1/4000, or to mercury oxycyanide 1/4000. The irrigation should be continued daily till the discharge had ceased or was manifest only as a morning drop—a stage usually reached in three or four weeks, when the irrigation could be gradually discontinued. In acute gonorrhœa the use of detoxicated vaccines had not been good. In the treatment of acute posterior urethritis the rules of general treatment should be strongly impressed; it had been found wiser not to begin posterior irrigation till the acute stage had subsided. A constant watch should be kept on the prostate in these cases. In all acute cases instruments and medicated bougies were to be avoided. The treatment of chronic gonorrhœa was a lengthy and often disappointing process, but modern methods, methodically and rationally applied, would cure almost every case. The secret of success was exact diagnosis, and only after all foci had been located should treatment be applied. The importance of regular prostatic massage was emphasised, and Dr. Fyfe described the use in diagnosis and treatment of such instruments as the urethroscope, the exploratory olivary bougie, the straight sound, the Kollman dilator, the suction apparatus of Mills, and the Ultzmann syringe. Treatment by vaccines alone was neither rational nor successful, though a better response to this treatment was obtained in chronic prostatitis than in any other condition of the chronic stage.

Complications and their treatment were then briefly dealt with, special mention being made of the magical effect of intravenous injections of electrargol in epididymitis, and finally Dr. Fyfe discussed the standard of cure. The four tests used in the Aberdeen Clinic were: examination for discharge, examination of the urine, examination of the prostatic secretion, and examination by the urethroscope. These tests should be applied at the completion of treatment, and then at monthly intervals for three months. Accessory tests were the provocative vaccine test and the complement-fixation test.

Discussion.

In the subsequent discussion there took part Mr. G. H. COLT, who referred to his experiences in treatment of the disease in Constantinople during the war, and pointed out the early symptom of itching of the glans penis; Dr. WILLIAM CHRISTIE, who emphasised the difficulties experienced in treating cases of gonorrhœa in private practice; Dr. R. RICHARDS, who stated that he had found the use of detoxicated vaccines helpful in the acute cases; Dr. GEORGE ROSE, who inquired as to the value of sandal wood oil; and the PRESIDENT, who in summing up the discussion laid great stress on the importance of the strict observance of the standard of cure and on the value of the urethroscope in diagnosis and treatment.

HUNTERIAN SOCIETY.—It has been decided that the annual award of the Hunterian Society medal, which for some years has been in abeyance, shall be re-established. The medal is awarded for the best essay on any subject which shall be submitted by any general practitioner resident within Great Britain, Ireland, or the Channel Islands, "whether Fellows of the Society or not." Essays should be sent to the hon. secretary, Dr. A. E. Mortimer Woolf, at 94, Harley-street, W., not later than Dec. 31st, 1924. The medal will be presented at the annual dinner of the Society in February following. The medallist will be expected to read his essay at the annual general meeting of the Society. The hon. secretary will forward all particulars to anyone desiring them.

Reviews and Notices of Books.

Diseases of the Nervous System.

A Text-book of Neurology and Psychiatry. Fourth edition. By **Smith Ely Jelliffe**, M.D., and **William A. White**, M.D. With 475 engravings and 13 plates. London: H. K. Lewis and Co., Ltd. 1923. Pp. 1119. 2 guineas.

The general plan of this well-known text-book, now in a merited fourth edition, is based on the conception of a division of nervous activities into three groups—vegetative, sensorimotor, and psychical—with corresponding defects of function which concern the endocrinologist, the neurologist, and the psychiatrist. Each constitutes a study and a specialty in itself, and if there are, in fact, comparatively few who claim to be experts, yet a working knowledge of each is requisite for success in the practice of any of the three. Aside from this standpoint, moreover, it is scientifically legitimate to claim that the different levels of dysfunction are but manifestations of impairment in a single unit—viz., the nervous system—conceived in its broadest sense. We have no sympathy with division of such morbid activities into watertight compartments which make passage from one to the other an unduly difficult proceeding; on the contrary, a text-book such as this serves a useful purpose beyond that which may be supposed to be its immediate purpose—it orients the inquiring mind in the direction of a conception of neural action one and indivisible, whatever form the outward expression of this action may take.

For its size the volume is sufficiently comprehensive for all practical uses; its many illustrations and tables facilitate its handiness from the viewpoint of descriptive neurology; there are numerous references to the literature to serve in further research. On the psychical side it is coloured by a definite Freudian cast, which is well illustrated in the statement that there is no pharmacotherapy for "genuine epilepsy"—in our opinion an unfortunate remark. The authors, however, are candid enough to see that a Freudian explanation of at least some mental diseases—e.g., dementia præcox—raises more difficulties than it lays. As far as the student is concerned we consider he should read the psychiatry section of the book with openmindedness, in view of the speculative nature of some of the authors' contentions; the professional reader will know just how much worth to attach to the more problematical of these.

Traumatismes du Poignet et Rayons X.

By **Étienne Destot**, of Lyons. Paris: Masson et Cie. 1923. Pp. 174. Fr.16.

Some 20 years ago there appeared a small work dealing with injuries of the wrist-joint which soon became recognised as the first complete and accurate radiological study of the various traumatic lesions which affect this region. During the years which followed its first publication, the author, Étienne Destot of Lyons, continued to assemble clinical and radiological records with a view to the production of a larger monograph on this subject. The manuscript was finished shortly before his untimely death in 1918, and it has fallen to the lot of four of his pupils to arrange for its publication. The wealth of material which forms the basis of the present work must surely be unique in the experience of a single observer. The book is divided into eight sections, as follows: (1) Anatomy and physiology; (2) sprains and scapho-semilunar subluxation; (3) fractures of the scaphoid; (4) dislocation of the carpus and mid-carpal luxation; (5) fractures of the semilunar; (6) uncommon fractures of other bones; (7) radio-carpal dislocation; (8) various types of fracture of the lower end of the radius.

The work may be regarded as a classic, and as time goes on much of its contents will be incorporated into the standard text-books of surgery and radiology. Until this happens an English translation would be of great value.

The Form and Functions of the Central Nervous System.

Second edition. By **Frederick Tilney**, M.D., and **Henry A. Riley**, M.D. With 763 illustrations, including 56 coloured. London: H. K. Lewis and Co., Ltd. 1923. Pp. 1020. £2 12*s.* 6*d.*

The favourable impression aroused by a perusal of this monumental work on its first appearance is substantiated on a glance through its new edition. There is little change from the earlier issue, except by way of incorporation of some helpful suggestions from those who have offered certain criticisms on various points. On the whole, it is strongest on the purely anatomical side; its physiology is based not a little on deductions from the clinico-pathological side—a method of great and undiminished value, but one which requires such amplification as it can obtain from the experimentalist. Detailed criticism would be out of place in a review of this character, for the technicalities of the work are of interest mainly to the neurologist and neuro-anatomist; our appreciation of the book, however, can be understood when we say it is more complete than Edinger's well-known "Vorlesungen," and much more modern than similar works that have been familiar to the student of neurology for the last 20 years.

Disease in Captive Wild Mammals and Birds.

By **Herbert Fox**, M.D., Pathologist to the Zoological Society of Philadelphia. London and Philadelphia: J. B. Lippincott. 1924. Pp. 665. 60*s.*

This work is a careful record of observations and deductions made during the past 20 years on all the mammals and birds which have suffered from disease or died in the Zoological Gardens at Philadelphia. The number of post-mortem examinations upon which the records are based was 5365; of these, 1860 were on mammals and 3505 on birds. In nearly all the large zoological gardens of the world a record of the routine post-mortem examinations is kept, but hitherto no attempt has been made to correlate the results, and this is the first time that such a record has ever been placed in a compact form before the members of the medical and veterinary professions. The original object of the work was the pursuit of knowledge for its own sake, but there is no doubt that the results have been of great practical value in the management of the Philadelphia gardens; hygiene has been improved, disinfection has been made scientific, epidemics have been arrested, and some diseases (e.g., tuberculosis in monkeys) have been entirely eliminated. Throughout the book the reader will be impressed by the way in which pathological findings are brought to bear on the diagnosis, treatment, and prophylaxis of disease. The relation of diet to disease is fully discussed in a chapter by Dr. E. P. Corson-White. An interesting table is given showing the pathological findings in relation to the dietary habits of animals. Birds and mammals which live on a mixed diet of plant and animal tissue show a lower percentage of disease of the digestive organs than those whose diet is purely carnivorous or herbivorous. Thyroid disorders are almost entirely confined to the carnivora; likewise the percentage of rickets was highest in young carnivora.

The section dealing with the incidence and significance of animal parasites emphasises the value of parasitological studies in zoological gardens, both in relation to the animals and to human beings. The early examination of the fæces of newly arrived animals for helminth eggs, and the subsequent treatment of infested cases with vermifuges, have considerably diminished the cases of parasitic enteritis and other disorders which are directly due to parasitic worms. Research on the morphology and bionomics of helminths collected after death from wild animals is being carried out at several of the larger zoological gardens, notably London and New York, and much fresh light is being thrown upon some of the common helminth infections of man by means of the study of comparative material. There is no doubt that researches upon other groups, of which a zoological collection offers a large variety, would be productive of similar good results.

The subject of tuberculosis in monkeys is dealt with at considerable length, especially from the diagnostic point of view. Owing to the difficulty in obtaining physical signs or demonstrating the tubercle bacillus in these animals, the tuberculin test is employed on every new arrival or suspected individual. Mixed bovine and human tuberculin is used, the initial dose for a monkey weighing 10 lb. being 1 mg. The variations in temperature are then taken per rectum at four-hourly intervals for 48 hours. In healthy animals there is no reaction; in tuberculous animals there is usually a definite rise in the first 12 hours, followed by a fall and a subsequent rise during the second 24 hours. The temperature of a healthy monkey is highest in the daytime during the period of greatest activity, and drops at night when the animal is at rest. Great reliance is placed on this reaction by the author, and animals which are found to be positive are not allowed to be placed on exhibit. The skin and eye tuberculin tests have been tried, but do not give reliable results. The chapter on neoplasms contains two valuable tables, one showing the type of tumour and organ of origin, the other showing the incidence in relation to sex, breeding, duration of captivity, metastases, embryological origins, and order of animal affected. The incidence of new growth was found to be highest among the rodentia and lowest among the primates, the marsupialia and carnivora came second and third on the list. The main organs affected were uterus, liver, thyroid, and mammary glands, in this order. In birds the kidney was found to be the commonest site of a primary growth. There are in all 28 very valuable statistical tables dealing with the incidence of disease, analysis of diet, and weight ratio of organs.

This is a book which merits the attention not only of the administrative staff of every zoological garden, but also of everyone interested in human and comparative pathology.

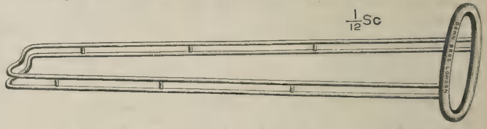
JOURNALS.

Journal of Industrial Hygiene.—The January number reports the proceedings of a joint meeting held in Buffalo between the American Association of Industrial Physicians and Surgeons and the Health Service Section of the National Safety Council. It contains a series of articles by industrial doctors dealing from experience with various aspects of occupational medical service. All are of interest, but the most useful is a description of the service established by the Endicott-Johnson corporation, employing 16,000 shoemakers. The service is complete and covers medical attention at work and at home. Each worker is examined on engagement and again six months later. A medical staff is always on duty during working hours; the medical centres had 90,000 calls in 1922, and the ambulance was in use 5000 times. A well-attended baby clinic for children of the workers is held weekly, of which pre-natal work is a feature. Dental and eye work is carried out. Nose and throat work is a specialty. The staff doctors paid 75,000 visits in the year to homes and the nurses 15,000. Convalescent homes for girls and for men are maintained. The total cost of medical service is placed at nearly $400,000 for 1922. The result is a family of happy, contented workers, who produce more finished material per worker than any similar group and have a very low labour turnover; labour disputes are unknown.—G. M. Price contributes a preliminary paper on the physical examination of 50,000 garment workers. The observations were made at the Union Health Centre, a unique, well-equipped clinic in New York, operated by workers on a self-supporting coöperative plan. One dollar is charged for examination and treatment; selected physicians received $7.50 for one and a half hours' attendance. Applicants for admission to the Garment Workers' Union are all examined medically. Only 45 out of 36,510 were rejected, but many were accepted on limited sick benefit. Two per cent. had some respiratory trouble, 1·5 per cent. had chronic heart disease, 15 per cent. gastro-intestinal disease, and 25 per cent. neurasthenia. Interest also attaches to the discussion notes referring to the papers read.—The February number contains an article dealing with physical examinations, with follow-up work, in a department store, by C. A. Swan and E. B. Emmons, which shows that only 29 per cent. of those examined had no defects, and that among the remaining 71 per cent. defects were found averaging nearly two per person. The authors hold that physical examinations are the first step in industrial preventive medicine and that the expense incurred is entirely justified by the results obtained in returns to the establishment.—D. R. Wilson contributes a valuable article on industrial lighting, in which he summarises in readable form the investigations which have been carried out by Government inquiry. The installation of lighting primarily is a question for the architect, but the standard to be attained is one which must be laid down by physiological research.—The action of irritant gases upon the respiratory tract is ably summarised by H. W. Haggard. He brings together available knowledge with regard to the various irritating gases which may occur industrially, and states the concentration at which they become dangerous, and the symptoms which result.

New Inventions.

AN IMPROVED SPLINT FOR FRACTURE OF THE FEMUR.

The routine treatment of fractured femurs, excluding the use of calliper traction, has not always yielded satisfactory results. At the present time extension by means of adhesive plaster with the limb supported on a Thomas or Hodgen splint is probably the method most in use. Quite frequently, however, there is some displacement of the fragments which extension fails to cure, and I have lately used a modification of the ordinary Thomas's knee splint, which has proved useful in correcting displacements which have persisted after reduction of the fracture and fixation by extension. As the illustration shows, the alteration consists in the addition of an extra bar fixed to the ring of the splint. Small metal struts maintain the distance between the two bars. The limb is supported on one ring and, by suitably arranging bandages on the upper bar, any lateral or antero-posterior displacement may be corrected. Thus where the upper fragment is adducted and flexed a bandage placed over it under the top bar and pulled tight will control the flexion. The use of a splint slightly bent at the knee is an additional aid. To overcome the adduction another bandage encircles the thigh above the site of fracture and is used as a lever with the outer bar as a fulcrum. A similar bandage is applied in the opposite direction below the site of fracture. The advantage of the extra bar is that it affords more opportunity for simple manipulation than the conventional single bar. The bandages should be of stout material, such as drill.



Messrs. Down Bros. are the makers of the splint.

George Sacks, M.B., B.Ch. T.C.D.

General Hospital, Swansea.

THE LANCET.

LONDON: SATURDAY, APRIL 19, 1924.

MATERNAL MORTALITY IN CHILDBIRTH.

THE publication of the Ministry of Health report by Dr. JANET CAMPBELL upon the results of an inquiry into the question of maternal mortality must serve to concentrate attention upon one of the most serious problems which confronts the medical profession to-day. Whilst the general death-rate has been reduced since the beginning of this century by almost one-third, and the infant mortality-rate during the first year of life actually halved, it is a matter of concern that the maternal deaths associated with childbirth are practically the same to-day as they were 20 years ago. That the problem is very real will be appreciated from the fact that approximately 3000 mothers in England and Wales lose their lives annually from what should be a purely physiological function. In a recent issue [1] we reviewed briefly Dr. CAMPBELL'S work, but the importance of the issues involved calls for a further reference to this valuable and painstaking report, a document which should be in the hands of all interested in the well-being of women and children, and which for this reason has been issued at the modest price of 1*s*.

The factors in the causation of this excessive mortality, as the report points out, are numerous and complex. Puerperal sepsis in its various forms accounts for by far the largest number of deaths. Next in order come the toxæmias of pregnancy, and finally, hæmorrhage takes its toll of victims. In all these conditions it is obvious that factors are at work which, in the words of the report, "are more or less directly controllable and should be controlled." In other words, the problem with which the country is faced is rather one of organisation and education than of principles directly concerned with current obstetric practice. That it is possible to conduct midwifery satisfactorily, and with little or no maternal mortality, even in the humble and insanitary dwellings of the very poor, is proved conclusively by the reports of the extern departments of the various lying-in charities. In the clinical report of the Rotunda Hospital for 1922–23 recently issued we note that in the extern department in a series of 1824 cases the maternal mortality was 0·21 per cent. In the same report, dealing with the intern department, Dr. G. FITZGIBBON calls attention to the evil results of bad midwifery in the following words: "Several cases were admitted in a moribund state, while five were admitted profoundly septic after protracted or complicated labour." Of considerable interest in this connexion is Dr. CAMPBELL'S observation that insanitary surroundings have probably much less direct influence upon puerperal mortality than is generally supposed, and that unless infection is introduced from without it does not appear that a woman who is accustomed to a low standard of living is more prone to develop sepsis after an ordinary confinement than one in a more hygienic dwelling. Even if this is the case, there can be little doubt, however, that uncleanliness and insanitary dwellings may and do spell disaster in the event of any obstetrical operation being necessary. The practitioner confronted with the treatment of a difficult complication in the presence of insanitation, overcrowding, deficient water-supply, or lack of effective lighting cannot apply those surgical principles which are so essential to prevent disaster. It is in this connexion that adequate antenatal supervision is so all-important. In the prefatory note by Sir GEORGE NEWMAN to the Ministry's report the fact is made abundantly clear that no sound progress can be made in the reduction of maternal mortality apart from antenatal supervision. It is an astonishing fact that the event of childbirth, the most clearly foreseen of all "illnesses," is inadequately prepared for. How often does an expectant mother "book" with her selected doctor, midwife, or maternity home, but fails to submit herself to the only safe method of control—namely, systematic antenatal supervision?

Antenatal supervision implies a competent knowledge of all the accidents that may befall a woman during her pregnancy and labour, and this requires a very thorough training not only in theory but in practical obstetrics. The General Medical Council has taken cognisance of this fact in its recent recommendations and resolutions in respect of the professional examinations, assigning to the training of midwifery and gynæcology a status not inferior to that of medicine and surgery. The medical schools are to-day taking steps to put these resolutions into effect, and the practitioner of to-morrow will not be able to say that he was taught surgery which he never practised and that he practised midwifery which he had never been taught. With improvements in the education of the medical student, a better training of the midwife must go hand-in-hand. Inasmuch as the responsibility of the maternal welfare is shared equally between the medical profession and the midwives, it is of the highest importance that the training of the latter should qualify them adequately to accept such responsibility. Since the passing of the Midwives Act in 1902 it is a matter for regret that so little improvement, if any, has been noted in the maternal statistics. In a series of 256 unselected cases of puerperal fever recorded by Dr. CAMPBELL, in an appendix to her report, it is noted that 102 cases occurred in the practice of midwives alone, as against 86 in which delivery was effected by a doctor. Figures such as this point to the importance of securing for a pupil-midwife the best possible training over a sufficiently long period. What this period should be is a question which has continued to engage the attention of the Central Midwives Board since the Midwives Act was passed. There is no doubt that the original period of three months' training was inadequate, and it is perhaps questionable whether the present revised regulations are sufficiently stringent to deal with the grave problems involved. When it is remembered that puerperal sepsis is the main cause of maternal mortality to-day, and that it takes the medical and nursing professions many years to assimilate the tenets of antiseptic and aseptic technique, it is asking a great deal of an uneducated woman to accept and practise those canons at the end of a few months' training. We are in absolute agreement with Dr. CAMPBELL in aiming at the total abolition of the so-called handy woman, and with the suggestion that there should be much closer coöperation between the doctor and the trained midwife. Coöperation on the lines suggested by Dr. JOHN FAIRBAIRN of shifting to the midwife those parts of medical service which are least essential, and relieving her of the responsibilities of those which are most essential, would go a long way in removing many evils which at present exist. Every prospective mother should have the advantage of a considered medical opinion during her pregnancy, although the actual conduct of normal labour might safely be left in the hands of an efficient midwife. In other words, it is the duty of the medical profession to prevent disaster, and prevention can only be secured by adequate preparation and supervision. Midwifery so conducted should not unduly tax the time of any doctor, since antenatal and postnatal observations can, in the words of the report, "be carried out without conflicting with the claims of other patients"; a very important factor in the day of the busy general practitioner. By contrast the time and energy that have to be devoted to coping with individual cases which, for whatever cause, have been allowed to progress too far without supervision is great indeed. Such cases form the bulk of those to which the practitioner is summoned by the midwife in distress, and we propose shortly to issue a special supplement designed to help him to deal with them. With the adoption of an improved antenatal and midwifery service on coöperative lines between midwives and practitioners, increased facilities must also be provided for dealing with obstetric problems. Where danger is anticipated there should be no obstacle in securing the services of adequate assistance whether it take the form of accommodation of a hospital bed, the provision of efficient nursing, or the help of a skilled obstetrician.

---

[1] THE LANCET, April 5th, p. 716.

The report of the Ministry calls attention to the fact that the returns of large cities such as Birmingham, Manchester, and Liverpool, where maternity work has been organised over a long period, show that systematic efforts over the whole country would undoubtedly lead to an appreciable saving of maternal life and health. It should not be impossible to overcome the financial and other difficulties involved in the building of a complete maternity service. A great deal has been accomplished within recent years in the reduction of infant mortality, and it can be anticipated with confidence that a similar concerted effort would result in a like benefit to the mothers of the nation. Dr. CAMPBELL is to be congratulated upon the work she has accomplished in accumulating such a mass of evidence and putting it forward in such a convincing manner.

◆

THE THERAPEUTIC SUBSTANCES BILL.

ON April 8th the Therapeutic Substances Bill was read a second time in the House of Lords. Under its provisions the manufacture and sale, by those who are not medical men, of vaccines, sera, salvarsan and its substitutes, insulin, and pituitary extract can only be carried out in this country under licence granted by the Minister of Health, and importation from abroad is restricted in conformity. Few of the many vaccines, sera, toxins, antitoxins, and antigens are at present capable of accurate titration. The potency of diphtheria and tetanus antitoxins, however, can be determined with a high degree of accuracy. In respect of these substances, powers similar to those sought for under the proposed Bill were secured in Germany in 1896 and in the United States in 1902. Diphtheria toxin to be used in the Schick test for susceptibility and toxin-antitoxin mixtures for immunising purposes should also be carefully evaluated before they are sold. There are, as yet, no accurate well-established methods for determining the potency of therapeutic sera such as anti-dysentery serum and anti-pneumococcic serum, and in the case of vaccines all that is possible at present is to determine the number of organisms in a certain volume of the preparations. The firms manufacturing antitoxins and vaccines in this country are of high reputation and have supplied trustworthy products for many years, so that it may appear that the need for the control of the supply of these substances is not urgent. At any time, however, similar products may be imported from abroad, and in the absence of such legislation as is contemplated there is no means of ensuring their purity and potency. There is reason to suppose that steps to control all these preparations will be welcomed by British manufacturers.

For the remaining substances, except pituitary extract, control of a temporary nature exists already; a fortuitous circumstance has in the case of salvarsan and insulin enabled advantage to be taken of the patent laws to obtain a check on the manufacture. In the case of salvarsan, the circumstance was the outbreak of war; at that time the supply of German salvarsan was cut off, and British manufacturers who had facilities for making it applied to the Board of Trade for licence to do so, in order to protect themselves from the possibility of post-war litigation for infringement of German patents. It was made a condition of holding such licences that the products should be subjected to biological tests designed to exclude unduly toxic samples, to be carried out by the Medical Research Council. After the war this arrangement came to an end, and as a result of Board of Trade negotiations the manufacturers continued production with licences granted directly by the German patentees. Biological control of salvarsan and neo-salvarsan would then have stopped but for the circumstance that the Ministry of Health was the largest purchaser of these substances; on this account the German makers were induced to insert in their licence to British manufacturers a clause providing for biological control of all products of this nature. At present, therefore, the accident of the war has enabled the Ministry of Health to persuade the German patentees to demand from the British makers biological control. To such circuitous courses does the absence of legislation lead. However, in a short time the salvarsan patents expire, and, as matters stand, the present checks will disappear; those who are familiar with the reports of the Salvarsan Committee are aware that it will be easy in that case for serious changes in the toxicity and therapeutic value of the preparations to occur, however carefully and conscientiously the chemical preparation is effected.

Control exists at present also for insulin, but again because of the accident that the original patent-holder is the University of Toronto, a body concerned to see that the manufacture of insulin is carried out for public rather than private interest. The patent rights in this country were offered to and accepted by the Medical Research Council for the very reason that as no legislation such as this Bill contemplates existed in England, it was only by holding these rights that any control over the efficiency and uniformity of the product sold could be maintained. There are those who have expressed doubts whether the part played by the Medical Research Council made for a rapid and adequate supply of insulin to diabetics; to such we may recommend an inspection of the state of affairs in France, where, in the absence of central expert control, the insulin supply still remains inadequate, untrustworthy, and expensive. It is not sufficiently realised that the large-scale manufacture of products such as insulin and pituitary extract is a comparatively new problem, which is almost as much outside the realm of a pure chemist as is a surgical operation, so that even the large manufacturers of drugs have been for the most part without the skill and experience necessary to deal with it. For pituitary extract there is at present no control, consequently the position as regards uniformity of potency is chaotic. A year and a half ago a report of the Medical Research Council stated that of five samples supplied on request by different manufacturers, the activity, as tested by the power to produce contraction of plain muscle, varied from 80 to 1. The reason for this discrepancy was in part due to the absence of a standard, and in part to the lack of any indication from the clinicians to the manufacturer of the suitable strength at which extracts should be made. At a conference in Edinburgh in July last of the leading pharmacologists of all countries (under the auspices of the League of Nation's Health Committee) to discuss international standards for biological products, a standard for pituitary extracts was adopted for investigation. If subsequently this standard is recommended by the League of Nations to the different governments, such recommendation, so far as this country is concerned, will be useless unless the provision in the Therapeutic Substances Bill becomes law.

We need not dwell further on the dangers arising from the present position. It is not surprising that accidents are reported in the use of pituitary extract in obstetrics when so wide a variation exists between the potency of different preparations; it is clear that a practitioner, accustomed to the use of one preparation, who for some reason changes to another, runs a serious risk of administering a dose much larger or much smaller than he intends. Practitioner and patient alike require the protection which this Bill proposes to confer.

PUBLIC HEALTH WORK BY THE LEAGUE OF NATIONS.

THE Covenant of the League of Nations established a machinery for bettering relations between Governments and for coördinating their action, not only in connexion with questions of keeping the peace, limiting armaments, and the many other political functions with which the League is ordinarily associated, but also in the work of the different technical organisations which have been set up under its auspices. It was fitting, therefore, that the Minister of Health should have been present at the lecture given by Dr. L. RAJCHMAN at the Royal Society of Medicine last week on the Health Organisation of the League, and should have introduced the subject by a most instructive preliminary address from the point of view of his Department and of the British Government generally. Mr. WHEATLEY drew attention to the fact that the formation of the Ministry of Health five years ago carried with it a closer association between the Government and medical and health questions than had existed previously; not only in his own department but in those specially concerned with medical research and the hygiene of schools and factories, all of which must be taken into account when reviewing the position of public medicine as a whole in this country and its relations to the State. Every one of these developments involves fresh points of contact with corresponding work in other countries, sometimes administrative when international understandings and agreements are needed, but more often educative, to make the experience of one country available for the others. While medical science has always been truly international and its practitioners have found their own ways of learning from abroad with little or no aid from the State, there are certain spheres in which there can be no question of the advantage which can be derived from the existence of an effective method of bringing together the different national public health services in the way which the Health Organisation of the League of Nations is now attempting. The establishment of a suitable body for this purpose has required some little time and negotiation, but it may now be regarded as completed, thanks to the fortunate arrangement by which the League will now be able to utilise the work and experience of the Paris International Health Office as part of its organisation; and it has already started with two exceptional advantages; the participation of the public health services of countries which ordinarily are thought of as being outside the League of Nations—the United States, Germany and Russia; and the special interest of the Rockefeller Foundation, which has supplemented the League's slender budget for health purposes (about £33,000) by donations for particular purposes.

Dr. RAJCHMAN was able in his lecture to outline the work which now lies before this Organisation and to speak of some results already achieved. The multifarious activities to which he referred appear to have become capable of this broad classification: (1) international agreements on health questions; (2) "standardisation"; (3) the comparative study of disease; (4) educational courses; and (5) official international coöperation for the prevention of epidemics. It is well known that the last-named of these activities bore very good fruit in Eastern Europe in connexion with the recent great epidemics in Soviet Russia, and it is satisfactory to learn that this type of work is to be extended to deal with the very notable increase of malaria which has taken place during the last two years in that country and in the Balkan States. Among the recent international agreements which already stand to the credit of the International Health Office is that which provides for the gratuitous treatment by modern methods of sailors suffering from venereal diseases at different ports of the world, the revision of the International Nomenclature of the Causes of Death, and a great deal of preparatory work in anticipation of the much-needed recasting of the International Sanitary Convention of 1912, the principal document governing the practice of quarantine. The work of "standardisation" is exemplified by the arrangements for joint expert studies and conferences which have led to the uniform adoption of the Ehrlich standard for diphtheria antitoxin, and have already brought us much nearer to general agreement on units and tests for various other therapeutic serums and products, including the glandular preparations which were specially studied by the League of Nations Health Conference last year in Edinburgh with the active participation of the Medical Research Council. Similar progress has been made with the comparison of values of the Wassermann and flocculation tests for the diagnosis of syphilis, recently carried out by representative bacteriologists at Copenhagen under the direction of Dr. TH. MADSEN. The nature of the educational courses has been illustrated during the last two months by the visit of some 50 foreign medical officers, from 25 different countries, to take part in a system of demonstrations of British health work organised by the Society of Medical Officers of Health; demonstrations which besides general public health work have included the specialist requirements of tuberculosis officers and school medical officers. A number of similar courses in which British medical officers have participated have already been held in foreign countries, and this year these will be continued in Switzerland, Holland, and Denmark while, as a further development of the same principle, arrangements are being made for conferences of medical statisticians for mutual study of the conditions under which the vital statistics of different countries are obtained. As one outcome of these statistical comparisons the Health Committee of the League has appointed a subcommittee, with experts attached, to investigate the causes of certain notable variations in death-rates from cancer, as reported from different countries.

It must be concluded from Dr. Rajchman's lucid account that a goodly number of vessels have been launched and that some of them will have a long and difficult course before they come into port. But though the programme which the Health Organisation has set before itself is an extensive one, it clearly gives an indication of the work being pursued in a thoroughly practical spirit. It is encouraging, moreover, to note the care which seems to be given to the selection of those undertakings which are appropriate to the League of Nations machinery and can hardly be effected without it. Mr. Wheatley reminded the Society that the Organisation had its birth in the British Ministry of Health in 1919. The progress since made is greatly to the credit of the handful of public health administrators from different countries who then laid down the main objectives of the Organisation and have since given so much labour and thought to its development.

Annotations.

"Ne quid nimis."

RADIOGRAPHIC METHODS IN THE LOCALISATION OF SPINAL AND CEREBRAL TUMOURS.

The complete diagnosis of tumours of the central nervous system is notoriously difficult. With spinal tumours the doubt arises as to the nature of the lesion, and consequently whether the patient can be relieved by operation; with cerebral tumours the chief difficulty is one of localisation. Hitherto we have been entirely dependent for localisation on our very incomplete knowledge of spinal and cerebral physiology, but recently two methods depending on radiography have been introduced—lipiodol injection, for spinal lesions, and pneumo-ventriculography for cerebral lesions. The injection of lipiodol into the spinal theca was first used by Sicard and Forrestier in Paris about a year ago and soon afterwards by Sargent in this country, and it has already been applied to a large variety of spinal cases. Lipiodol, a compound of iodine with a lipoid substance obtained from black-poppy pods, is a heavy fluid, very opaque to X rays, and apparently harmless to the nervous system. The method of using it consists in injecting 1 or 2 c.cm. by means of an ordinary lumbar puncture needle either into the lumbar theca, in which case the lipiodol is made to flow slowly towards the upper parts by tilting the subject, head downwards, at an angle of about 45 degrees, or between the occiput and the atlas into the cervical theca, in which case the lipiodol flows downwards. In either case any site of compression is shown radiographically by an arrest of the passage of the lipiodol, and the shape of the shadow produced may give important information as to the nature of the compression. The value of such a procedure is obvious: it may confirm or correct the "physiological" localisation, it may be of the greatest help in deciding the desirability of operating on a given case, and it may show the longitudinal extent of the compression which the surgeon has to deal with. The only danger attached to it arises when the sub-occipital site of injection is employed, and then it is that of sub-occipital puncture in general. The lipiodol itself seems to be innocuous; if no operation be performed it is allowed to remain in the theca and it gives rise to no symptoms; it is absorbed very slowly, if at all, for its presence has been demonstrated three months after injection. The difficulties of the procedure are merely those of taking X ray photographs of a patient in a slanting position, few X ray departments being equipped with tables that can be set at any desired angle. This difficulty can be overcome if the patient be placed in what Sicard calls "the position of the Mohammedan in prayer"; the injection can be performed and the radiograms taken in this position.

The procedure that has been introduced for cerebral radiographic diagnosis is pneumo-ventriculography. Its object is to show, by means of stereoscopic radiograms, changes in the shape of the lateral ventricles caused by the pressure of a tumour; and in order that the ventricles may be seen in an X ray photograph, the cerebro-spinal fluid in them is replaced by air. There are two very different techniques. Weed and Dandy, in America, introduced the method of direct puncture of the ventricle through a trephine opening in the parietal bone. With the patient lying on what was believed to be the affected side, they made a puncture on the other side of the brain and drawing off about 5 c.cm. of fluid at a time, they replaced it by air until 25–30 c.cm. of air were introduced; then they took a radiogram or set of radiograms; the patient's head was then turned over and the air made its way, via the foramina of Munro, into the lateral ventricle of the affected side, when a second skiagram was taken. The body of the ventricle might be greatly narrowed or completely occluded by a tumour in the parietal lobe, while tumours of the frontal, occipital, or temporal lobes would cause occlusion or distortion of the corresponding ventricular horns. Weed and Dandy claimed that by using this method they had not failed to localise any of a series of 200 cerebral tumours. The procedure has not found favour in this country; but, at the meeting of the Section of Neurology of the Royal Society of Medicine, reported on p. 803, Mr. Geoffrey Jefferson and Mr. A. A. McConnell were each able to give their experiences of it and to point out the difficulties. They found that in some cases the air did not find its way easily from one ventricle to the other and bilateral puncture had to be performed, that the amount of air introduced was insufficient, and that a definite mortality was attached to the operation.

An alternative technique comes from Germany and has been even less used in this country than the American method. At the meeting referred to, two speakers described varying success with it. In this method the puncture is made into the lumbar theca while the patient sits upright, and the cerebro-spinal fluid is drawn off 2 or 3 c.cm. at a time and replaced by air until 70–100 c.cm. of fluid have been withdrawn; then stereoscopic radiograms are taken of the skull. It is found that some air finds its way into the ventricles so that a ventriculogram is obtained. Such a procedure is certainly not free from danger, for in the case of tumours of the posterior cranial fossa the withdrawal of the spinal fluid is very liable to lead to the formation of a fatal conus cerebellaris. Yet one German neurologist has been able, obviously by a careful choice of cases, to perform the operation in 250 cases of various kinds without a fatality; in most cases there was no more untoward result than a severe headache, but in a few cases fits and febrile disturbances occurred. It seems probable that with improvement of technique some method of encephalography may lead to developments both in cerebral surgery and in our knowledge of cerebral physiology.

THE NURSE'S CURRICULUM.

An inquiry from the chairman of the Committee on Nursing of the Buffalo Academy of Medicine concerning the attitude of the Public Health Committee of the New York Academy of Medicine[1] on the matter of nurse training has led to a series of recommendations which will doubtless be regarded in certain quarters as reactionary. The report submitted by the committee emphasised the following points: 1. That the training course of nurses should be shortened considerably and should not cover a period of more than two years. 2. That there should be a revision of the curriculum, and that more stress should be laid on the acquisition of practical experience, and a better balance established between the various branches of nursing work than exists at present in actual practice. 3. That the first year of training should be so arranged that students who are compelled to discontinue their training for causes other than moral or mental deficiency may qualify as nurse attendants and should be eligible for licence examinations as such. 4. That graduate nurse attendants should be allowed to work in hospitals in order to increase further their proficiency and relieve the nursing shortage which now exists in many institutions. 5. That in planning a revision of the curriculum in nurse training schools the advice and guidance of the medical profession should be sought. The committee is likewise of the opinion that the Nurse Training School Council of the Board of Regents, in addition to its present membership, should include representatives of the trustees of hospitals. These suggestions are to some extent in line with the recommendations of the committee appointed by the Rockefeller Foundation.[2] This Rockefeller committee also recommends a reduction of the course at the hospital training schools to 24 months, preceded by four months' training in the basic sciences and in elementary nursing procedures; but this recommendation is dependent on the elimination of routine duties of no educational value and implies not a lowering, but a raising of standards. It is not clear whether the New York Medical Academy have designed their policy in the interests of the nurse or in those of the hospital service, for no suggestion is made that the shorter course should be more concentrated. Indeed, Clause 3, with its emphasis on the acquisition of practical experience, is not encouraging in this respect. Clauses 3 and 4, relating to nurse attendants, are unlikely to find favour in the nursing profession. While many agree that some sort of subsidiary nurse is needed by chronic cases who cannot afford and do not require the continued skilled attention of a fully-trained nurse, a rigid separation of the conditions under which they are taught is essential if confusion as to their status and competence is to be avoided.

THE WASSERMANN AND SACHS-GEORGI REACTIONS IN MALARIA.

Dr. G. Marcialis,[3] of the Medical Section of the Sassari Civil Hospital, reviews the literature, and records his observations on the Wassermann and Sachs-Georgi reactions in 225 cases of malaria, which were classified as follows: benign tertian, 44; quartan, 58; malignant tertian, 71; chronic malaria, 40; malarial cachexia, 12. Both the Wassermann and Sachs-Georgi reactions were negative in all the cases of benign tertian alike during the febrile attacks and in the intervals between the attacks. With one exception in which it was feebly positive during the attack, the Wassermann reaction was negative in all the 58 cases of quartan malaria, and the Sachs-Georgi reaction was negative without any exception in this group. The patient with a feebly positive Wassermann reaction was a child with no history or clinical evidence of syphilis, inherited or acquired. Of the 71 cases of malignant tertian the Wassermann reaction was strongly positive in five, both during the attack and in the apyrexial intervals, but these patients were also syphilitic subjects. In three with no history or evidence of syphilis it was feebly positive during the attacks only and not in the intervals. The Sachs-Georgi reaction was positive in ten cases, in five of which there was no history or evidence of syphilis during the attack and in five during the intervals. Both reactions were negative in all the cases of chronic malaria and malarial cachexia, during the attacks as well as in the apyrexial intervals. Injection of quinine in the syphilitic cases with the ordinary doses had no effect on the specific reactions in the serum, nor did the addition of large quantities of various quinine salts have any effect on the reactions of syphilitic serum in vitro. In connexion with this case allusion may be made to a fatal case of æstivo-autumnal malaria recently reported by Dr. G. McConnell,[4] of the Cleveland City Hospital. The patient was a man, aged 48, with a positive Wassermann reaction, in whom there was no clinical evidence of syphilis in spite of a history of infection 25 years previously. The necropsy, however, showed very definite syphilitic lesions of the aorta. Dr. McConnell remarks that previous statements to the effect that a positive Wassermann reaction may occur in malaria apart from syphilis were largely based on clinical examination only. The experience at the Cleveland City Hospital has been that when a necropsy has been performed on a patient with a positive Wassermann reaction veritable syphilitic lesions are always discovered.

THE ÆTIOLOGY OF SUMMER DIARRHŒA.

DURING the past decade or two widely divergent views have been put forward to explain the attacks of diarrhœa which infants are peculiarly susceptible to in the hottest summer months. Bacterial activity in milk before it reaches the consumer is held responsible for this kind of diarrhœa by some, while others trace it to the pyrexia which exposure to the sun may alone induce. Evidence in support of the latter view is put forward by Prof. Arvo Ylppö, of Helsingfors, in *Acta Pœdiatrica* (1924, vol. iii., fasc. 2, p. 213). The incident which prompted his investigations occurred on a warm day early in May, 1920, when a dozen prematurely born infants were given an over-exposure to the sun. All developed pyrexia, the temperatures of the three youngest infants, who were less than three months old, ranging from 39·6° C. to 40·5° C. Later in the same day they suffered from diarrhœa and vomiting. It seemed likely that the normal chemical reactions within the stomach and intestines had been upset by this bout of fever, and to throw further light on this problem Prof. Ylppö investigated the acidity of the gastric juice of several infants before and after the induction of pyrexia. He induced pyrexia by putting infants in a bath the temperature of which was gradually raised to 41°–42° C. After staying in this bath for 15 to 20 minutes, the infants were put in a hot pack which had been wrung out in water at a temperature of 45° C. In another series of experiments pyrexia was induced by the intracutaneous injection of calf lymph intended for vaccination. This lymph was diluted with sterile normal saline solution in the proportion of 1 to 10, and injected into the skin of the thigh at two points, 0·1 c.cm. being introduced at each point. The fever thus provoked occurred seven to ten days later, and lasted for one to five days. In both series of experiments it was found that a considerable proportion of the infants showed an appreciable lowering of the acidity of the gastric juice during the period of pyrexia. Prof. Ylppö suggests that even a temporary reduction of the acidity of the gastric juice provoked by a transient bout of pyrexia may prove fateful to the infant who happens to harbour pathogenic germs, such as those of the typhoid and dysentery groups, in the summer months. It has been shown that with a pH about 4 the gastric juice destroys these germs, and that with a pH about 5 the growth of these germs is considerably inhibited. In some of Prof. Ylppö's experiments the pH showed figures as low as 5·6–5·8, at which level of acidity the gastric juice exercises only a negligible bactericidal action on the germs of the typhoid and dysentery groups. These interesting observations afford some clue to the genesis of diarrhœa caused by parenteral injection or infection.

VACCINE TREATMENT OF EPIDEMIC ENCEPHALITIS.

AT a recent meeting of the Société de Thérapeutique of Paris, MM. A. Marie and Poincloux[1] reported the results of treatment of eight cases of Parkinsonism, following epidemic encephalitis, by intraspinal injection of the fixed virus of encephalitis. After removal of cerebro-spinal fluid, 1–5 c.cm. of a centrifugalised emulsion of the brain of a rabbit which had died of experimental encephalitis was injected. The emulsion represented a dilution of 1 in 20 of a virulent brain which had been kept in the ice-chest for 24–48 hours before use. The injection was followed by a rise of temperature ranging from 101·2° to 104° F., signs of meningeal irritation, cerebro spinal lymphocytosis, and a change in the clinical condition. The rise of temperature occurred 20 hours after inoculation, and lasted 24–36 hours, when the temperature fell to normal, except in two cases in which it remained between 100·4° and 102·2° for a week. The emulsion of a normal brain or of a virulent brain which had been inactivated by heat did not produce any rise of temperature. Signs of meningeal irritation consisted of pain in the head and spine, nausea, vomiting, pains in the limbs, and in one case Kernig's sign. The cellular reaction was always a lymphocytosis, which in several instances was very intense. Cases in which clinical improvement took place were those in which the temperature was highest and lymphocytosis was most marked. As regards results, two of the cases had to be excluded, as the patients refused further treatment after only two injections. Their present condition, however, is better than before, and at least tends to show the harmlessness of the method. Of the six others, two presented no improvement, while four had made remarkable progress. One patient in particular was able to get up, dress herself, read a little, and play the piano, which she had not done for four years. The writers suggest that even better results might be obtained if this treatment were adopted at the onset of encephalitis, and that it might possibly be of prophylactic service in epidemic times.

THE TREATMENT OF LEPROSY.

THE subject of leprosy engages more than ordinary attention and interest at the present moment on account of the energetic measures that are being taken for the eradication of this dread disease in the British Empire, and Sir Leonard Rogers, chairman of the Medical Committee of the British Empire Leprosy Relief Association, reviews in the March number of the *Tropical Diseases Bulletin* (Vol. XXI., No. 3) the recent literature dealing with the malady. The *Bulletin* further outlines the scope and object of the campaign against leprosy, showing how the medical policy is directed towards extending the application of improved methods of treatment throughout the Empire, not only by supplying the necessary drugs, but also by training those in charge of lepers to apply them. Researches on the ætiology and treatment of the disease are encouraged, and support is given to sound schemes of segregation. The method by which the work is carried out is illustrated by Dr. H. W. Wade, in a paper dealing with the Culion Leper Colony in the Philippines. Prior to May, 1921, he states, the staff was insufficient to enable any systematic treatment amongst the 4500 lepers to be undertaken, but in 1923 it was possible to record systematic observations on selected cases to the number of 4067. Intravenous injections of Rogers's original preparations were soon dropped on account of venous troubles, and in their stead chaulmoogra esters, plain or iodised, were injected intramuscularly. A survey on Sept. 30th, 1923, showed improvement in 55·9 per cent., while in a further 36 per cent. the disease had been checked; 6·4 per cent. of the cases showed retrogression, and in 1·7 per cent. of the total death occurred. Further progress of this crucial test will be watched with great interest. The principles underlying treatment are set forth in a paper contributed by Dr. G. E. Muir. He believes it is necessary to strengthen the body resistance and to induce repeated small reactions due to the breaking up and setting free of the bacilli in the tissues—a process which must be carefully controlled. A rise of temperature may be beneficial, and a case is quoted in which the leprotic lesions disappeared with the onset of kala-azar. Muir believes that injections of hydnocarpate esters into the skin lesions causes the most rapid improvement, and concludes that early and persistent treatment arrests the disease and causes gradual disappearance of the signs and symptoms. In an informative and careful study on prophylaxis, Rogers sums up the matter by saying that the main point is the avoidance of contact between lepers and healthy individuals, and, in order to do this successfully, cases must be detected in an early stage of the disease. Instances are given of the good effects which have resulted from segregation in Norway, Sweden, Iceland, and Eastern Canada.

CULTIVATION OF MICRO-ORGANISMS IN TISSUE PLASMA CULTURES.

S. B. Wolbach[1] and M. J. Schlesinger, encouraged by the work of H. Zinsser [2] and E. G. Carey on rat leprosy, have succeeded in obtaining what they believe to be a multiplication of rickettsia organisms in guinea-pig plasma-tissue cultures. The strain of Rocky Mountain spotted fever virus was maintained for over a year in guinea-pigs, while that of typhus was originally brought from Poland and was maintained by passage in the laboratories at Harvard. Special technique was devised, guinea-pig tissues being employed throughout; in the case of Rocky Mountain spotted fever the testicular and in the case of the typhus the brain tissues were used. Blood from half-grown guinea-pigs provided the source of the plasma and a technique was adopted which permitted the collection of blood, its centrifugalisation and a separation of the plasma with as few manipulations as possible. The tissue for cultivation was obtained with aseptic precautions and kept immersed in Ringer's solution until the plasma was prepared; then portions for culture were cut into pieces 0·5 to 1·0 c.mm. in size. When tissue cultures were transferred to fresh plasma, in order to prolong the period of growth, the pieces of tissue were removed from the plasma, washed in sterile Ringer's solution, transferred to fresh sterile cover-slips, and fresh plasma added. In this manner tissue cultures have been kept in active growth for four to six generations, over a period of four to six weeks. For injection into guinea-pigs the tissue cultures were teased into pieces small enough to pass through a No. 18 gauge hypodermic needle. The fragments of tissue underwent fairly prompt degeneration. Endothelial cells tended to congregate at the periphery and the only blood cells which survived for more than a few days were eosinophiles. The nerve cells underwent rapid disintegration. From tissue culture fixed and sectioned at intervals it was possible to follow the growth of the micro-organisms and to note their increase in numbers in endothelial cells in the vessel walls. The effect of the micro-organisms on the cells themselves appeared to be deleterious; it is evident that the cells containing them rapidly die, and the life of the organisms in turn is dependent upon that of the endothelial cells. In the case of Rocky Mountain spotted fever occasional filamentous forms of *Dermacentroxenus rickettsi* were observed. In the case of typhus the cells containing *Rickettsia prowazeki* congregate at the periphery of the tissue. The forms most frequently found are exact replicas of those encountered in lice fed upon typhus patients.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE Charter of Incorporation granted to the London School of Hygiene and Tropical Medicine, as mentioned in our news columns last week, carries into effect the stipulation of the International Health Board of the Rockefeller Foundation of New York, made in offering to provide and equip a School of Hygiene in London, by associating the proposed school with the University of London. The Charter lays down generally the constitution of the new body and appoints a provisional board of management who are to take steps for the erection and equipment of such a school, pending the appointment of a permanent governing body, and to form a first board of management for a period of not more than 18 months. The appointment of a fresh board of nine members after that period is provided for, and there is to be in addition a court of governors consisting of 35 members. Provision is made for the amalgamation of the existing school (the London School of Tropical Medicine) with the newly incorporated school, which will take over the work and functions of the existing school together with its equipment, laboratory, library, and museum, devoting to the purposes of tropical medicine a sum not less than the income of endowments for that purpose of the existing school at the date of transfer. The Charter further provides for the taking over of the staff of the existing school by the London School of Hygiene and Tropical Medicine, and for that body contributing to the cost of reconditioning the premises in Endsleigh Gardens of the Seamen's Hospital Society, if those premises are vacated by the existing school by reason of the amalgamation. As long as the Seamen's Hospital Society maintains a hospital for tropical diseases at Endsleigh Gardens, the London School of Hygiene and Tropical Medicine, so far as may be practicable and to such an extent as may be agreed upon, is to make use of the hospital for the clinical instruction of students of tropical medicine.

TREATMENT OF SYMPTOMATIC SCIATICA.

IT has long been recognised that one of the causes of sciatica may be arthritis or periarthritic trouble about the hip-joint. Indeed, some writers have gone so far as to attribute to this cause a majority at least of the cases of sciatic pain. In a paper on the Orthopædic Treatment of Symptomatic Sciatica, published in the *Journal of the American Medical Association* of March 22nd, Dr. Philip Lewin, of Chicago, attributes the symptoms of most of his cases to lumbo-sacral or sacro-iliac disease, and describes a method of treatment which is essentially the same in principle as that generally used for disease of the hip-joint. It involves extension by weight and pulley and physiological rest in bed, followed by ambulatory treatment, in which a plaster spica and a high boot on the sound foot and crutches are used, and finally, after cure a special thigh and loin corset is to be worn. Dr. Lewin has treated thus about 50 cases, most of which were cases of lumbar or lumbo-sacro-iliac osteo-arthritis. The results, he says, have been very satisfactory. Of late years much attention has been given in the United States to the diagnosis and treatment of sacro-iliac disease; many more cases have been reported in that country than in Great Britain, where definite arthritis of the joint from whatever cause arising is comparatively rare. The climate of the Eastern and Middle States of the Union is more extreme than that of our islands, and the seasonal alternation of severe cold with considerable heat may possibly be answerable for the amount of arthritic disease noticeable there. Many of the cases of sacro-iliac disease which have been described in American publications have been of slight severity, yet sufficiently disabling to drive sufferers to seek surgical relief, and it is these patients who are liable to suffer the machinations and thaumaturgical performances of quacks. The evidence of underlying arthritis may easily be overlooked, and we would call the attention of British surgeons to Dr. Lewin's paper as well as to others on similar affections of the spine and pelvis.

LUNACY LAW: THE HARNETT CASE APPEAL.

THE arguments in this case, which is again adjourned, have been reported at considerable length in the daily press, and no comment upon the proceedings, which would be permissible, would supply readers with any information which they have not before them. The discussions point to a judgment which will define for such cases in the future what measure of protection is extended by the existing law to those who sign certificates of lunacy, and if that measure is seen to be too scanty, we may assume that amendment of the law will follow. A comprehensive volume[1] on the law relating to lunacy appears at this opportune moment. The book is the result of the author's 15 years' experience as Master in Lunacy. Sir Henry Theobald deals in order with the royal prerogative in relation to lunatics, administrative control by various authorities, the functions of Judge and Master in Lunacy, of the Chancery Visitors, of the Board of Control, and of Poor-law authorities. The many points of contact of the lunatic with the general law are also dealt with at some length. While willing to forgo the word "lunacy" in legal proceedings and documents intended to be brought to the notice of patients, the author desires to retain the word "asylum" as concise, of pleasant sound, and with ancient association. The author's blindness has left without a cloud the mental vision which makes this tome a real compendium of knowledge on lunacy law.

Sir Humphry Rolleston has been re-elected President of the Royal College of Physicians for the ensuing year.

WE regret to announce the death on April 13th of Dr. Hugh Walsham, consulting radiologist to St. Bartholomew's Hospital, London.

THE memorial to the late Prof. Sir G. Sims Woodhead at the Cambridgeshire Tuberculosis Colony, Papworth Hall, which has taken the form of a new pathological laboratory and X ray department, will be opened on Thursday, May 8th, by the Hon. Sir Arthur Stanley The hospital, hostels, workshops, and village settlement will be open to visitors from 2 to 4 30 P.M.

AT the Royal Society of Medicine hospitality will be extended to a new movement of a modest character—which is not to say that it may not develop. A small show of artistic work by medical men will be on exhibition in the Marcus Beck Room of the Society from May 26th to June 14th, and will be open to Fellows and Members of the Society and their guests and friends. The President of the Society is promoting the exhibition, Dr. Cuthbert Lockyer acting as hon. secretary, while Mr. Sydney Kendrick has kindly consented to select the work and supervise the hanging of the pictures.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXVII.—THE TREATMENT OF SPRAINS.

ALMOST every structure in the body is subject to strain which, if repeated, or if of undue severity, is liable to produce pathological change. In this article, the effect of undue strain will be considered mainly in so far as it affects the extremities. Here the structures concerned are joints and muscles.

Joint Injuries.

Locking.—The simplest form of sprain of a joint consists of a plain locking following on prolonged muscular effort, or sudden twist or jar. There is no actual displacement, but movement is rendered painful, and the extreme range is probably limited. If the part affected is, for instance, the wrist, a sudden shake undoes the locking, the pain vanishes, and a transient discomfort alone is noticed. In severer injuries the unlocking is less easily performed, and pain and disability may persist in varying degree. This condition when occurring in the knee furnishes a typical example of cases which yield such brilliant result from so-called " bone-setting manipulation." Locking of the sacro-iliac joint (traumatic lumbago) is far more common than is supposed, and is very disabling. The pain can be relieved by manipulation followed by supporting the joint with a belt. A detailed account of the manipulations suitable to reduce the locking of the various joints will be found in an article entitled Bone-Setting (THE LANCET, 1920, i., 301).

Synovitis.—If the force to which the sprain is due is of sufficient severity to damage any of the structures which compose the joint, synovitis will usually follow, and probably ligamentous structures will be injured. The joint need not be immobilised because synovitis is present. Indeed, recovery will probably be far more rapid without unrelaxed fixation. But a sharp distinction must be drawn between the prescription of movement and of function. For instance, in the ordinary traumatic synovitis of the knee, a systematic dose of exercise of the muscles controlling the joint, and of movement of the knee will hasten absorption; but if the weight-bearing function of the knee is added to the movement, recovery will be delayed. The ideal treatment for this condition is to apply wool in large quantities round the joint (a half-pound roll of cotton-wool, fluffed out before the fire is not too much), over which mass a bandage is very firmly applied. If pressure is applied over an insufficient quantity of wool, circulation is impeded.

The idea of the application is to exert sufficient pressure on the joint to check further effusion, and, while not preventing movement, to limit it. Frequent muscle contraction, and movement so far as the pressure will allow, are then practised freely; but weight-bearing should not be allowed until the fluid is absorbed. Graduated faradic contraction is useful while effective voluntary contraction is impossible, but should not be allowed to replace it.

Torn Ligaments.

If on examination after a sprain some point of special tenderness can be discovered at a point not directly over the joint line, it is probable that some ligament has been torn. Even then there is no need for absolute fixation unless the tear is severe enough to allow displacement of the joint, but it is all the more important to prohibit function as distinct from movement. Except at the extremes of anatomical movement in a joint, no strain is laid upon the ligaments during movement. Thus a limited movement will allow repair of the torn ligament to take place while hastening the absorption of fluid and maintaining the circulation in the muscle.

Immediately after injury, pressure should be exerted over the sensitive spot by the pad and bandage already described, and, in addition, a thick pad of some non-resilient material, such as felt, should be applied over the sensitive spot, the pad being covered with adhesive plaster with the adhesive side outermost to prevent slipping. When swelling has disappeared and function is prescribed, it is well at first to support the injured structure. For example, a wedge should be placed on the inner side of the heel if the internal lateral ligament of the knee has been torn, or a corresponding wedge on the outer side if the external lateral ligament of the ankle has been injured. It is wise to limit movement by strapping; as recovery takes place full anatomical range should be allowed once a day, with the strapping removed.

The rest position of injured joints must be studied so that the action of gravity so far as is possible is obliterated. Thus in the treatment of a sprain of the acromio-clavicular joint, the weight of the arm in the upright position must be borne by supporting the olecranon firmly upon a sling, and movement must be practised only in the recumbent position. Similarly, the wrist should be treated on a short, cock-up splint between the intervals allowed for prescribed movement; this should be performed with the patient recumbent and the forearm vertical, the hand being deviated towards the side of the injured structure. The fingers should be treated during the period of rest in the flexed position. During the periods of rest the knee should be slightly flexed, and the patient encouraged to lie so that the external ligament is kept under tension if the internal lateral ligament is involved, and vice versa. The ankle should be supported at a right angle, slightly inverted or everted, according as the internal or the external ligament is damaged. A severe sprain of the shoulder may lead to disastrous results, and if abduction cannot speedily be regained in the recumbent position, the use of an abduction splint should be advocated in the acute stage. When this can be discarded the olecranon should be supported. The movement prescribed should only be performed in the recumbent position, with the weight of the arm supported on the floor or table. A severe sprain of the elbow should always be treated on conservative lines; for, although X rays may show no injury to bone, a comparatively trivial injury may often result in a massive formation of new bone if an attempt is made to hasten recovery unduly, and this may seriously impede restoration of function. The limb should be supported in the flexed position in a sling, with the extended thumb resting upon one side of the neck and the fingers on the other. When swelling has disappeared epicondyle restoration of movement may be regulated by placing a " collar " round the neck and a " cuff " round the wrist; the two are strapped together by a tape, the length of which is increased day by day. If it is found one day that the original position of flexion cannot be secured voluntarily, the flexed position should be gradually restored and the limb rested in this position for a few days, when the attempt may be renewed.

Dosage of Movement: Massage.

Increase of pain or swelling, or decrease in mobility means that too much freedom has been allowed. While pain and swelling are decreasing, and painless movement is increasing, it is safe to advance. Pain on movement means irritation of the joint, or undue strain upon a damaged ligament.

Massage.—If the injury has been severe there will almost certainly be a painful reflex protective spasm of the muscles controlling the movement of the joint. Massage skilfully applied is the correct remedy and should begin well away from the affected area. It may even be advisable to start with massage of the thigh when the ankle has been injured. As relief is experienced the injured part may be gradually approached. Only stroking and gentle kneading movements should be employed, becoming more delicate as the sensitive area is approached. The aim of the massage is to relieve muscle spasm, and so to render painless voluntary contraction possible. The use of the pad and bandage, and of strapping, is a means of exerting a sort of auto-massage of the injured part every time that movement takes place. A layer of stockinet between the strapping and the skin is of advantage, especially in those with sensitive skins. The strapping must be laid over the surface of the skin so as to exert no pressure, the object being: (1) to form an inextensible skin; (2) to limit movement.

Passive Movement.—If the injury has been very severe, passive movement may prepare the way for active movement. Passive movement, however, can be performed only after complete muscular relaxation has been secured by massage, and must be absolutely painless, or reflex contraction of the antagonists will occur and complete relaxation is no longer present. Any movement which is then performed is a forced, and not a passive, movement, and will do far more harm than good. The same applies if the movement lays any strain on a torn ligament. Provided the patient's sensory tracts are not diseased, no movement which does not elicit pain can do harm.

Torn Muscles.

If a muscle is torn as the result of a sprain, it is important to prevent adhesions from forming between the injured fibres. Treatment should begin with massage to allay spasm, and the pad and bandage or strapping is then applied according to the severity of the injury. If voluntary movement is inhibited by pain in spite of massage, faradic stimulation should be applied until voluntary action is fully restored.

Chronic Sprains.

A tendency to repeated strain means either that the supporting ligaments of the joint have been permanently stretched as a result of previous injury, in which event nothing but adequate support will prevent recurrence; or that some or all of the muscles which control the stability of the joint have lost power, and then perfect recovery will follow the building up of the muscle strength. If persistent pain is a sequel to the sprain of joints or muscles, and certain movements provoke pain, adhesions are usually present, and must either be stretched or broken down. If a muscle only is involved, stretching will sometimes follow faradic contraction or suitable exercises. If a joint is involved, occasionally restoration can be accomplished by means of massage, manipulation, and exercises; but, as a rule, manipulation under an anæsthetic is required for complete cure. This means that some abnormal structure must be torn across—that is, the re-infliction of an injury—which must be treated as a recent sprain of the part. In cases of sacro-iliac or lumbo-sacral strain these two remedies are insufficient and support is called for. In tennis elbow constant trauma may have caused a small bursa to form underneath the origin of the muscle. The bursa can sometimes be cured by inserting a needle into it and passing a galvanic current of 5 to 6 milliampères for five minutes through the needle. If this fails the patient must put up with the disability or have the bursa removed by operation. A chronic strain of the shoulder (as found in pitchers at baseball, and in lawn-tennis players) will often defy treatment, and effectively prevent further participation in the game. The trouble is probably due to a recurring sub-deltoid bursitis, and the only remedy (short of excising the bursa) is for the patient to practise abduction in the recumbent position at frequent intervals during the day, always stopping short within the limit of pain. Ionisation or diathermy relieve pain and may hasten recovery. In other cases operation may afford the only chance of relief.

A Warning.

When considering a severe strain, if there is any possibility that bony injury may have taken place, an X ray should be taken to exclude fracture. In the later stages, before forcible manipulation is undertaken, it is always wise to have the joint X rayed again, since if traumatic osteo-arthritis is advancing, it is often wiser to avoid all forcible movement.

THE TUBERCULOSIS SOCIETY:
MEETING AT CAMBRIDGE.

A MEETING of this Society was held in Cambridge on April 10th, 11th, and 12th, with Dr. E. Ward, the President, in the chair.

A Comparison of Tuberculosis in Man and Animals.

Dr. Louis Cobbett, in his paper on this subject, pointed out that not only the distribution, but the very appearance of tuberculosis varies greatly in different animals, and that in the rat, for example, tubercles look more like sarcoma or lymphadenoma than the familiar tubercles of man. The rat is the least sensitive of all animals to tuberculosis, tolerating enormous doses of tubercle bacilli. But there are limits even to the rat's resistance, and an intraperitoneal injection of 50 mg. of tubercle bacilli ultimately proves fatal. Though there may hardly be any macroscopic lesions demonstrable in such a rat, a smear from any of its organs shows enormous quantities of bacilli. Dr. Cobbett demonstrated numerous photographs and slides showing how in the lung of the ox, for example, tags or villi develop on the surface, which assumes a shaggy appearance like that of a rough towel. On the liver, however, these superficial tags become flattened and mushroom-like. A point he emphasised was the difference in the susceptibility of the various organs in the animals subject to tuberculosis. In the rabbit, for example, the lungs and kidneys seem to be most susceptible, whereas in the guinea-pig the liver and spleen come first in this matter, the kidneys proving to be remarkably resistant.

Developing the theory that it is the highly specialised and hard-worked organ which is most subject to tuberculosis, Dr. Cobbett gave an account of tuberculosis in the mammary glands of different animals. In the cow the mammary gland has become highly specialised and hard-worked because for thousands of years she has been bred by man for her milk-producing qualities. These qualities have now reached a pitch when the cow produces more and richer milk than her own progeny can digest, and Dr. Cobbett gave an amusing account of a controversy between himself and an attendant employed by the Royal Commission on Tuberculosis to feed the experimental animals. Against the advice of this attendant Dr. Cobbett gave the calves the run of their mother's milk, with the result that the calves died, their intestines being found stuffed with undigested curds. The cow has had to pay the penalty for this specialisation of her mammary glands with reduced resistance to tuberculosis in them; about 2½ per cent. of all cows suffer from tuberculosis of the udders, whereas mammary tuberculosis in the human race is exceedingly rare. Similar differences, depending on similar reasons, may be observed in the rabbit and guinea-pig. The rabbit breeds many young in one litter, and they are long dependent on their mother's milk. Hence the comparative susceptibility of the rabbit's udders to tuberculosis. The guinea-pig's udders are practically never tuberculous, and in this connexion it is noteworthy that the young guinea-pig depends on its mother for its food for only a brief interval. For the same reason the hard-worked, highly specialised brain of man is more subject to tuberculosis than the brain of the lower animals, and the comparative frequency of tuberculosis in the heart of the dog may be associated with the sudden and violent calls made on this organ by the dog. Other factors determining the occurrence of tuberculosis in various organs are their degree of exposure to infection and their capacity to retain tubercle bacilli or pass them on. With regard to the first of these points, the lymphatic glands are frequently tuberculous because they bear the brunt of the first attack; it is no discredit to them that they are tuberculous any more than it is a discredit to the police force that many of their members have broken heads. As for the second point, muscle tissue is remarkably free from tuberculosis, largely because it does not arrest tubercle bacilli which pass on. Dr. Cobbett referred to some interesting experiments on chemical affinities in connexion with the localisation of tuberculosis, and he pointed out how, when carmine is injected, it may adhere to the endothelium of some organs but not to that of others. Similarly the particles of fat in the tubercle bacillus may attract it to certain organs with a craving for the same fats. With regard to the problem of the conversion of one type to another, he thought that this process must be practically impossible for the definitely human and bovine types, and he emphasised the difficulties of experimental work in this field.

In the discussion which followed Dr. H. A. Ellis suggested that the problem of tuberculosis was largely one of acidity and alkalinity, the tubercle bacillus pining in an acid medium and when its host was fed on meat. He was convinced that all successful treatments are essentially acid treatments, being acid by virtue of increased metabolism. He referred to observations on tuberculosis on monkeys at the Zoo and the beneficial effects noted in the case of a tuberculous monkey fed on meat.

Experiences with Diaplyte Vaccines.

Dr. E. Ward read a paper on this subject, prefacing it with a review of the researches which led up to the evolution of the diaplyte vaccine. In addition to observing over 60 cases treated with this vaccine in London, he had given it to 41 of his own patients, most of whom were in the third stage of pulmonary tuberculosis and were "hang-fire" cases. There were only one or two cases in the first stage of the disease. He had also tried this vaccine in a few cases of lupus and tuberculous sinuses. After detailing his dosage he reviewed the general effects. The temperature reaction was very varied; there might be no change, or the temperature might be lowered or raised, or it might be first lowered and then raised. In some cases there was an immediate rise of temperature, and in others there was no change in the temperature, but an increased pulse-rate showed that the vaccine was doing harm. He had also seen the vaccine have a cumulative effect, the delay in the ill-effects of the vaccine not saving the patient from a very serious reaction. In several cases there was a considerable interval between the injection and the focal reaction, in the judging of which Dr. Ward insisted that the ear is more likely to be deceived than the eye. Headache, anorexia, general malaise, pain, pleurisy, hæmoptysis, and attacks of phlyctenules recurring regularly after each injection were but some of the ill-effects recorded, and many of his cases had terminated fatally. He had come to the conclusion that his observations on man were confirmatory of those of Dr. E. H. Kettle [1] on the guinea-pig, but he adumbrated the possibility of obtaining better results by modifying the technique —i.e., changing the dosage and the spacing with a view to eliminating the injurious effects of the focal reaction. He referred in appreciative terms to the stimulating effect which Dreyer's work has had on this subject, and he hoped that further knowledge of the spacing of doses of tuberculin would help to solve the problem of graduated exercise. At present the cumulative effects of frequent injections of tuberculin and graduated exercise, continued daily, struck him as injurious.

Dr. F. E. Gunter compared the action of the older tuberculins with that of diaplyte vaccine, and he discussed the relation of a high blood pressure and fatness to specific treatment. In some cases he had found a change from tuberculin to diaplyte vaccine do good. Asthmatics, he had found, derive great benefit from tuberculin, to which thin patients react less satisfactorily than fat patients. Mr. G. R. Girdlestone referred briefly to his experiences with diaplyte vaccine in surgical tuberculosis, and, like Dr. Ward, he stressed the desirability of ringing the changes on the dosage and spacing in the hope that better results may be obtained. Though he had seen no focal or general reactions, he could not, on the other hand, positively affirm that the diaplyte vaccine had done good. Dr. H. G. Trayer had treated 60 cases, nearly all pulmonary, with diaplyte vaccine. Of 25 sputum-positive women patients, 14 were improved, 4 were as before, 2 were definitely worse, and 5 were dead. Of his 35 male patients, 33 were sputum-positive. There were only 9 improved and 7 were as before. Five were worse and 14 were dead.

More than one speaker congratulated Dr. Ward on the fairness and impartiality of his paper.

Tuberculosis Work in America.

On Friday, April 11th, Dr. R. C. Matson, of the National Tuberculosis Association of America, gave an account of American tuberculosis work in general and of the activities of his Association in particular. Many of the speakers who followed him gave their own views and experiences of tuberculosis work in America, and he, in winding up the debate, had some interesting comments to make on what he had seen of tuberculosis work in England. He said that the Christmas sale of tuberculosis seals or stamps in America was first started in 1908 in coöperation with the American Red Cross, only 5 per cent. of the proceeds being devoted to the expenses of the central organisation. The rest of the money was spent in the localities in which it was raised. It was calculated by his Association that there ought to be a bed for every annual death from tuberculosis, but at present the ratio of beds to annual deaths in the U.S.A. was only 70,000 to 100,000. It had been calculated that there were nine active cases and nine latent cases for every annual death. There were about 700 sanatoriums, 595 dispensaries, and 11,000 tuberculosis nurses. There had been a reduction of the tuberculosis death-rate from 202 per 1000 in 1910, to 94·2 in 1922. Pirquet and intracutaneous tests carried out by Dr. C. H. Smith on 3500 children at the Bellevue Hospital Clinic had shown that only 40 per cent. of the 15-year-old children were tuberculin-positive. Similar findings in St. Louis and Philadelphia were in marked contrast to the 75 per cent. positive findings of various centres in Europe less than a generation ago, and it is evident that the morbidity as well as the mortality is coming down with a run in the U.S.A. Dr. Matson gave an account of the almost innumerable activities of his Association and the way in which every aspect of the problem is being scientifically and systematically tackled.

Answering various questions and criticisms, he referred in particular to European misconceptions as to the spitting habits of the average American. Whatever these may have been a generation ago, it was certainly no longer easy to spit in public, even out of doors. To do so in a tram was to ask for trouble. He did not believe that any connexion had been demonstrated between smoke abatement in the towns and the decline of tuberculosis. As for the differences in the tuberculosis rates among the various races in the U.S.A., he suggested that these differences were not merely racial but economic; these rates were high among Jews, Irishmen, and Norwegians living in poor areas, while they were comparatively low in richer areas inhabited by the same races. As for sanatorium construction, the present tendency is to prefer large, solidly constructed buildings to small extemporised sanatoriums, the efficiency and administrative cost of which leave much to be desired. He criticised the system, adopted in parts of England, of not trusting the patient; in the U.S.A. the patient is taught as much about his disease as possible, to take his own temperature, and more or less to become his own physician. In this connexion he described the steps taken to educate the public by articles in such periodicals as the *Journal of Outdoor Life*, which devotes its columns to the exposure of fake consumption cures, and to instilling the principles of hygiene. Other matters referred to were the decline of tuberculosis due to bovine infection in New York, this decline being associated with the pasteurisation of milk. Other problems touched on were those of tuberculosis in the negro, after-care, the indigent and migratory consumptive, and the effect of climate and altitude on the incidence of tuberculosis. In this last matter it is significant that as much as 30 per cent. of all the deaths from tuberculosis in Colorado occur among the natives.

---

[1] THE LANCET, Jan. 12th, 1924, p. 68.

Dr. S. Roodhouse Gloyne anticipated that popular health literature, as exemplified by the American *Journal of Outdoor Life*, would not appeal to the Englishman sufficiently to give the publisher a return for his money, and he argued that the psychology of the British and American not being identical, it would be unwise to assume that what was sauce for one would be so for the other. But both he and Dr. E. Ward, who spoke on the same subject, recognised the value of popular education by the printed word. Dr. Gloyne's references to the differences between the two countries in the matter of provision for research were an oblique tribute to the public-spirited attitude of the Americans. Dr. Matson promised to give information at the Wembley Exhibition about the Framingham demonstration.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Bacterial Flora of Paper Money.

PAPER money has been till recently the only currency in the hands of the public. A bacteriological investigation of paper money carried out by Dr. Kiefer, and published in the *Archiv für Hygiene*, is therefore of great practical interest. He explains that minted coin is not only from a financial point of view but also for bacteriological reasons preferable to paper money. Coined money is innocuous owing to the self-disinfecting action of the metal itself and because its small and smooth surface prevents the development of germs. The dirtiest piece of copper is from the standpoint of a bacteriologist better than newly-issued paper money. In post-war bank-notes which had been for some time in circulation 13,000 to 143,000 germs were found, whilst in pre-war bank-notes it had previously been proved that only 800 to 3000 germs were present. The reason is that previously to the war those notes were only little used and did not pass from hand to hand as at present. The number and the kind of germs was not influenced by the wear and tear of the notes, nor did the habitat of the notes matter whether they came from a butcher, a baker, or a candlestick maker. Notes which had been handled with wet fingers—e.g., in fishmongers' shops—were richer in germs, as in general dryness of the paper hinders bacterial growth. It makes a great difference, however, whether the bank-note consists of soft or of laid paper, the latter offering more opportunities for the germs to stick to the paper. The author has made investigation into the vitality of the germs and found that streptococci were virulent 54 hours, whilst enteric fever bacilli lived 11–96 days, *Bacillus dysenteriæ* (Shiga) 17–52 days, and *Staphylococcus pyogenes aureus* 93–127 days. Various infectious diseases may thus be spread by paper money more frequently than by any other article in use among the people.

Transfer of Medical Practices.

Compared with the state of things in England the transfer of practices for money is rather rare in this country and no professional agents exist who negotiate such transfers. The reason is that the German law does not sufficiently protect the purchaser of a practice against breaches of the contract by the vendor. In the official journal of the Leipziger Verband a very remarkable case of that kind was lately published where a doctor had purchased the practice and also hired a part of the house of another medical man under the condition that the vendor should abstain from practising in the respective town and its surroundings. Notwithstanding the clear provision of the contract, the vendor four weeks later began to practise again in the part of the house where he had continued to live. The purchaser then applied for an injunction at the local law court that the vendor be ordered to abstain from so doing under penalty of a large fine. The judge, however, declined to give the injunction, declaring that the provision by which the vendor had to abstain from practising was invalid. He summoned both parties before the court, and to avoid the high expenses and the long duration of a law-suit they came to an agreement of which the most important provisions were that the purchaser had to leave the house as soon as a new residence had been provided for him by the authority dealing with the distribution of dwellings (Wohnungs-Amt), that the vendor might take up practice again, but that he had to pay to the purchaser 25 per cent. of his income from club practice. The legal adviser of the Leipziger Verband, who was asked for his opinion in the case, has made the following statement: The decision of the judge was quite in accordance with numerous decisions of the High Court of Justice. That court has decided that a provision of a contract preventing a medical man from practising must be regarded as immoral and thus null and void. It is in the public interest that a doctor should carry out his medical practice and that consideration must always have priority to the private interest of a purchaser: when a vendor begins to practise again he is, of course, liable to repay the sum or part of it to the purchaser. Although the vendor cannot therefore be prosecuted in a civil law court for such breach of the contract, he is nevertheless responsible for his action to the medical court of honour, because by agreeing to a provision under the mental reservation to break his promise he has acted against the most elementary principles of medical ethics.

The Danger of Malaria Treatment in G.P.I.

The Minister of Public Health drew the attention of the medical profession to the fact that the treatment of general paralysis of the insane by injections of malaria germs—a method devised some years ago by Vienna alienists—may have the drawback that malaria, which for many years has been non-existent in Germany, may again be spread and become endemic. This is the more so because the anopheles by which malaria is conveyed is found nearly everywhere in this country. Medical men who administer the malaria treatment must therefore carefully protect the patients against the bite of the anopheles mosquito. The district medical officers of health are instructed to register every case of malaria and to investigate its origin and its possible connexion with the treatment of G.P.I.

Economy in Prescription Writing.

The sick-clubs had complained that they had great financial difficulties in bearing the enormous cost of medicines and drugs prescribed by the profession. At a recent meeting of the German Board of Public Health, a consultative body connected with the German Health Office, the matter was discussed at the request of the above office. Four members—namely, Prof. Kraus, of Berlin, and Prof. Müller, of Munich, as physicians, Prof. Jadassohn, of Breslau, as dermatologist, and Prof. Straub, of Munich, as pharmacologist, read papers on the subject. As a result the Board expressed the following opinion: that under the present bad condition of German finances in general, and of the legally instituted sick-clubs in particular, it was the duty of the medical profession to restrict the prescribing of medicines and of dietetic compounds as much as possible. Amongst compounds of equal efficacy they should choose always the least expensive, the prescription should be made in a plain form, and complicated combinations avoided. Compounds which are legally allowed to be sold without a written prescription should be given preference over others. Patent medicines ought to be avoided as much as possible and German drugs be preferred to foreign ones, because they are, as a rule, cheaper, being exempt from duties. It must, however, always be considered that an expensive drug, if more efficacious than a cheaper one, is preferable to the latter, because it shortens the time of the illness and thus makes the patient sooner able to work. Modern medicines ought to be prescribed only when their value has already been proved by competent physicians, by systematic research in hospitals and university clinics.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

AMONG the earliest annual health reports for 1923 to reach us are those of three boroughs, some of the principal statistics of which are given in the following table:—

Name of borough.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Bootle (C.B.) ..	81,580	24·5	13·1	1·7	0·9	3·1	35	85	2·0
Hornsey (B.) ..	88,325	13·8	10·5	0·7	1·6	1·9	31	52	4·0
Poole (B.) . ..	43,860	19·3	11·9	1·4	1·6	1·1	31	60	2·4

Bootle.

Dr. F. T. H. Wood states that housing remains the most pressing of the public health needs of the borough. No houses were completed by the council during 1923, but it is proposed to build 100 during 1924. It is estimated that 988 houses are required to bring the housing of the Bootle population up to the 1911 standard for the whole population of England and Wales. A tabular statement shows a marked excess of tuberculosis in Bootle since 1913, and that the rate since the war has been higher than in 1913-14. A wireless installation has been provided out of voluntary funds for the entertainment of the patients at the Linacre tuberculosis hospital. In the case of non-pulmonary tuberculosis the council maintain six beds at the Leasowe hospital for children, and also pay to the general hospitals for the treatment of adults. Venereal diseases, judged by the new cases applying at the clinic, have shown a steady decline since 1919. The total expenditure on these diseases for 1923-24 was £2135, and the council have joined with the Merseyside boroughs in a representation to the Ministry advocating that it be made a statutory obligation on sufferers to obtain treatment. It has been found necessary to increase the expenditure on free (dried) milk for mothers and infants from £250 to £300. The antenatal work grows, and during the year about one in six of the expectant mothers attended the consultations. Cases of threatened eclampsia, contracted pelvis, and syphilis were thus brought under timely treatment. The number of cases admitted to the maternity home was 109—39 for obstetric reasons and the remainder on account of unsatisfactory home accommodation. The cost of the maternity home for the year was about £1500, one-third of which was paid by the patients, the remainder being charged to the rates and Exchequer grant.

Dr. Wood points out that Bootle has the highest birth-rate of the 17 Lancashire county boroughs, but that, in spite of this fact, only three of them—viz., Southport, Blackpool, and Warrington—showed a lower infantile mortality-rate. One case of ophthalmia, which was not notified, was followed by blindness. An additional health visitor was appointed in April, and it was found possible to pay more than four visits to each baby, two visits to each child in its second year and one visit to each child between the ages of 2 and 5. The sessions at the infant welfare centres have had to be increased, and the Bootle Health Society has continued its valuable services in supplying voluntary workers, supplementing the milk assistance scheme, &c. Dr. Wood discusses the question of public health education. He attaches importance in the first place to the activities of health visitors and school nurses, and in the second place to the teaching of personal hygiene to the young during and shortly after school life, but propaganda work directed to the public in mass must not be neglected, and in pursuance of this latter aim addresses have been delivered during the year to various existing organisations at their periodical social or business meetings. The possibilities of the kinema and of broadcasting are also urged.

Hornsey.

Dr. A. T. Nankivell, in presenting his report, insists, like Dr. Wood, on the importance of public health education if we are to make further progress. Hornsey is, notably, not a self-contained town. The Census figures show that 27,534 persons leave Hornsey daily for their work, while, on the other hand, 5515 workers enter Hornsey daily. Such a daily movement of the population, Dr. Nankivell points out, often in crowded conveyances, gives great opportunities for the contraction of respiratory infections. During 1922 a mixed vaccine, designed to protect against colds, bronchitis, and pneumonia, was distributed for trial to 60 doctors in Hornsey, free of cost. Of the 60, only 21 replied to Dr. Nankivell's inquiry as to their experience of the vaccine, but of these 21 only one thought the vaccine was no use. Many of the replies are quoted and are so favourable that the experiment has been repeated this winter.

The report includes an interesting chart showing the death-rate, infant mortality, and neonatal mortality rates from 1883 to 1923. The chart shows that up to 1900 the infant mortality-rate remained unaffected by the decline in the general death-rate; that since 1900 the infant mortality has come down from the neighbourhood of 120 to the neighbourhood of 60, while the general death-rate has increased from about eight to 10 or 11; and that throughout this period of 40 years the neonatal mortality has remained practically the same with even a slight tendency to increase during the years since the war. In commenting on this last-named feature, Dr. Nankivell stresses the need for an extension of antenatal work, but also refers to the taking of drugs to bring on abortion as "a common and wide-spread practice," and a cause of infant death "well known to midwives, health visitors and doctors who are acquainted with maternity work." There are no areas in Hornsey which could be called slums, but here and there groups of dilapidated houses, sublet to several families, which need close supervision. For economic reasons the families living in these sublet houses will not be able to rent the houses which the council is preparing to build, and those who are thriftless and bad tenants would not be received into a corporation house. Dr. Nankivell mentions among the needs of Hornsey—a convalescent home, a residential open-air school, and the establishment of open-air classes.

An inquiry was made as to the prevalence of left-handedness among the school children, arising from the report of some of the head-teachers that this condition was prejudicial to the child in after-life. Among 6058 children examined, 239 were found to be left-handed and 87 ambidextrous. Of the 239 left-handed children, six had a stutter, 42 were dull and backward, 181 were of normal intelligence, and 16 more than usually bright. Of the 87 ambidextrous children, 15 were dull and backward, 69 of ordinary intelligence, and three above the normal in mentality.

Poole.

Dr. R. J. Maule Horne draws special attention to the extension of the water undertaking so as to give an ample reserve and to the sewering of two difficult areas which will enable many cesspools to be abolished. An estimate was made that in 1921 there was a shortage of 824 houses as compared with the 1911 standard. Since 1921 874 houses have been built or arranged for, and it is estimated that a further 250 houses are needed to provide for the natural increase of the population. Attention has been given to mosquito-prevention by spraying the likely breeding places with paraffin. The Poole milk does not come out well, when judged by a permissible standard of 20 parts of solid sediment per million parts of milk, as 19 samples out of 34 failed to pass this test. The analyst reports that eight out of 10 samples of butter contained an excess of water, and that a sample of lard (which ought to be free from water) contained 4·5 per cent. of water. He estimates that if all lard were similarly adulterated the population of the town would lose 2·8 tons of fat food in a year! The school report shows that the average school attendance has steadily increased from 86·1 per cent. in 1919 to 91 per cent. in 1923. Of 1199 children referred to the dental clinic, 966 (80·5 per cent.) actually attended and received treatment. Charges for treatment at the school clinic were only introduced during the year, so it is too early to speak as to the effect of the innovation.

Cardiff Port Sanitary Authority.

Dr. Ralph M. F. Picken reports that the prevalence of small-pox in Portuguese ports necessitated more than usual vigilance. The amount of shipping dealt with showed an increase over the past two years and the foreign tonnage has only been once (1916) exceeded since 1914. Twenty-eight nationalities were represented. Methods of inspection have to be very prompt, as vessels come in large numbers into five docks on the tide and go rapidly under the tips with a view to early departure. The work of the V.D. clinic at the Royal Hamadryad Seamen's Hospital has proved very valuable. The number of seamen attending for the first time, which reached its maximum (1234) in 1920, was 821 in 1923. The examination of 156 rats, caught on vessels or in warehouses, for evidence of plague, gave negative results. The number of rats destroyed during the year was less, but the campaign against them has not slackened, and Dr. Picken thinks the decrease may be attributed fairly to the increasingly efficient methods of rat destruction adopted at all ports throughout the world. *Xenopsylla cheopis*, the plague flea, was found in nine out of 21 rats from the Cardiff docks. The rats caught in vessels and warehouses at the docks are consistently of the black variety, while those found in the city are mostly brown. There is no evidence that the rat population at the docks is being replenished from the city. The drinking water of 210 ships' tanks was examined and reported to be satisfactory in 127 cases, of moderate purity in 41, of doubtful purity in 19, and contaminated in 23.

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 5TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely: Small-pox, 99; scarlet fever, 1336; diphtheria, 649; enteric fever, 38; pneumonia, 2025; puerperal fever, 35; cerebro-spinal fever, 13; acute poliomyelitis, 3; acute polio-encephalitis, 1; encephalitis lethargica, 190; dysentery, 14; ophthalmia neonatorum, 134. No cases of cholera, plague, or typhus fever were notified. The cases of encephalitis lethargica were notified in the following counties: London, 17; Chester, 9; Lancaster, 47; Northumberland, 9; Nottingham, 8; Warwick, 26; Yorks, W. R., 34; and elsewhere in smaller number.

Deaths.—In London, the deaths from diphtheria, which had been 10, 15, and 14 in the preceding three weeks, fell to 11 last week, and those from measles, which had been 98, 121, and 100 in the preceding three weeks, fell to 62 last week. The deaths from influenza, which had been 89, 83, and 49 in the three preceding weeks, further fell to 45 last week.

SCHICK IMMUNISATION IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a letter from the Secretary of the Anti-Vivisection Society in the *Brighton Herald* of March 22nd attacking the views of Dr. D. Forbes, M.O.H. of Brighton, from which a highly distorted inference would be drawn from the results of our experiences of the Schick methods in their application to the prevention of diphtheria amongst the staff of the Bristol Fever Hospital, as recorded by me in your issue of Oct. 6th, 1923.

Our results here have shown that, although a negative Schick reaction does not *always* mean complete clinical immunity to diphtheria, under the exceptional conditions to which fever hospital staff are exposed in nursing an unusually virulent and infective type of the disease, it certainly always indicates a comparatively high immunity. Although a few of our negative reactors contracted diphtheria, it was a very mild type of disease compared to the extremely severe attacks from which members of our staff were suffering previously to our adoption of Schick's method. In reference to artificial immunity conferred by toxin-antitoxin mixture, none of our staff who has had three doses of this mixture has contracted diphtheria since our using this method, extending over a period of 26 months. With two doses a few failures of protection were recorded.

As I consider that those in close and constant contact with this disease require a higher immunity than would suffice to protect those exposed to slight and infrequent exposure to infection in the outside world, I have been giving all joining members of our staff three doses of T.A.T. mixture before allowing them to nurse in the diphtheria wards without applying the Schick test to them. Up to the present none of these 32 new members so treated, who joined since last autumn, have contracted the disease, although daily exposed to a type of disease of high virulence. None of those inoculated during the past 26 months have evinced any serious symptoms whatever.

I am personally convinced that the general use of T.A.T. in schools would exercise a profound effect in reducing the mortality from this deadly disease, but it is wise to consider that, like everything else in medicine, those methods are not *absolutely* infallible.

I am, Sir, yours faithfully,

B. A. PETERS, M.D. Camb.,

Medical Officer, Ham Green Hospital, Bristol.

April 10th, 1924.

AURAL VERTIGO.

To the Editor of THE LANCET.

SIR,—The discussion on vertigo at the Royal Society of Medicine[1] left inevitably a sense of incompleteness, as time did not permit of any attempt to harmonise the views presented from so many different angles. As I understand it will not be resumed, I would like to touch on one or two of the points raised.

1. *Equilibrium.*—I was a little surprised that no one pointed out that perfect equilibrium is possible when the semicircular canals have been completely destroyed or rendered functionless by disease or operation, so that the afferent stimuli from them are wholly absent; vertigo does not result from the absence of those stimuli, but from their perversion; when there is a lesion of the canals of whatsoever nature, there is always a potential cause of vertigo; when their action absolutely ceases, equilibrium is restored. (I am assuming for practical purposes that equilibrium and vertigo are the converse of one another, which,

---

[1] THE LANCET, March 1st, p. 444.

as Mr. Fisher pointed out, is not quite true, the fact being, I think, that we use the word equilibrium to cover the physical state and the mental—i.e., the sense of equilibrium.)

Cyon showed long ago, in pigeons whose semicircular canals had been rendered completely functionless, that the Flourens phenomena did not occur. Apart from that, there are two facts as regards man which prove that equilibrium can be maintained without the aid of the semicircular canals: (1) One case certainly, and I think more, have been shown in the laryngological section in which the whole of the auditory apparatus had been extirpated on both sides, and yet perfect equilibrium was maintained. Further, the patient showed no vertigo and no nystagmus when rotated. (2) I believe that the same thing is true of all congenital deaf-mutes. I understand that they do not show vertigo with any of the ordinary tests, and they certainly are quite impervious to sea-sickness. I made inquiries at a large deaf-mute school in Brighton which I visited several times, and the master there, with 40 years experience, told me he had never known of a case.

As regards both these classes, we want to know what they lose apart from their deafness. Do they lose the sense of motion and direction in space (semicircular canals), or the sense of position in space (otoliths)? The value of the reflexes demonstrated by the Dutch investigators has to be considered carefully in this connexion. The Americans rejected from their flying corps all men who did not show the normal degree of instability when rotated, but whether this was only a general principle or was based on ascertained facts I do not know. If, as I believe, it is found that there is no serious drawback for practical purposes except deafness, we are driven to the somewhat painful conclusion that in the semicircular canals man possesses a beautiful and complex mechanism which has been superseded by higher development, and whose only positive function now is to produce some of the most disabling and distressing symptoms which the human body can experience; moreover, so bound up with the organ of hearing that it is impossible to remove it without inflicting the penalty of deafness. To further our knowledge on this point, we need, unless it has been already carried out, a systematic examination of the reactions of deaf-mutes, and of the effect on them of lesions which ordinarily cause vertigo (aural, cerebellar, &c.). Observation of the effect of an acute lesion of the fourth nerve in a deaf-mute might help to settle Mr. Fisher's doubt as to the directness of the effect of ocular lesions, and also, whether vertigo really occurs at all when the functions of the semicircular canals are abrogated, except in cerebral lesion.

2. *Aural Vertigo.*—When I read some 25 years ago the statement quoted by Sir H. Rolleston of Sir W. Gowers that nine out of ten of the cases "which seek advice for vertigo" have an aural lesion of some sort, I was rash enough to doubt it, and set to work to disprove it. After collecting something over 200 cases, I came to the conclusion that Sir W. Gowers was entirely right, and that the chances of an aural lesion being present are at least 9 to 1, though the proximate and apparent cause may be something quite different. I have to thank my friends the late Mr. Creswell Baker and Mr. A. T. Hutchison for their very kind help when there was any doubt about the ear.

It is impossible to give fully the conclusions I arrived at, much less the clinical evidence on which they are based, but I should like to state, very briefly without dogmatising, some of my own inferences.

(*a*) I believe that a patient with a permanent aural lesion, though long inactive, must be regarded as having a permanently lowered threshold for vertigo. They may never have an attack, or only at very long intervals due to some intercurrent cause which may be anything from transient dyspepsia to oncoming arteriosclerosis, but the liability is there.

(*b*) There are many causes which tend to produce slight attacks of vertigo—e.g., the climacteric, arteriosclerosis, ocular and digestive troubles; but where severe vertigo resembling the vestibular type occurs with one of these conditions, either constantly or alternating with lighter attacks, then an aural lesion is always present in addition.

(*c*) Owing to their intermittent character and the fact that the aural lesion may have been quiescent for years, the nature of aural attacks is often overlooked, unless the character of the vertigo is carefully inquired into. Like migraine, they may be concealed under the name of bilious or gastric attacks, and, rarely, may be confused with migraine where unilateral pain is present due to increased tension in a smouldering lesion.

(*d*) The causes which produce severe vertigo apart from aural trouble are quite rare; it is by no means constant in cerebral or even cerebellar tumours; the attacks in insular sclerosis are usually slight, and are not the cause of the falls which occur in that disease. Apart from this it occurs in ocular troubles, especially paralysis of the fourth nerve, and I am bound to add from my own experience, in functional disease, though very rarely. I have known two cases of neurasthenia, so-called, in which severe and disabling vertigo occurred; one was sent home from a tropical colony to an eminent London neurologist for operation as a case of cerebellar tumour. He had no signs of organic disease, and after some months' rest returned to his official duties.

(*e*) We do not know why, with lesions and conditions apparently identical, some people suffer from aural vertigo and some do not, or why they suffer at one time and not another. Some authorities, including the late Sir J. Goodhart, maintain that it only occurs in the neuropathic, but I do not think that this, though largely true, can be accepted absolutely. The fact that vertigo is found to be a normal sequel of certain tests has some bearing on this point. Moreover, the presence of a peripheral lesion differentiates it from epilepsy and migraine, though cases associated with nerve deafness are closely allied as to classification. To determine what proportion of those with aural lesions suffer from vertigo would be a very difficult matter for many reasons, some already stated. Only carefully prepared statistics from a large aural clinic would give us even an approximate idea.

I should like to enlarge on the practical importance of these points, and some others—e.g., the diagnostic value of vestibular tests—but I have already exceeded my limits. I am, Sir, yours faithfully,

EDMUND HOBHOUSE.

Brechin-place, S.W., April 7th, 1924.

GASTROMYOTOMY.

To the Editor of THE LANCET.

SIR,—The ideas expressed by Dr. T. C. Clare in his article[1] on gastromyotomy for the cure of gastric ulcer are of great interest. I should like to confirm them from another point of view. At the Yugoslavian Surgical Congress, held in September, 1921, Chief Surgeon A. Gottlieb read a paper[2] which may be unknown to British medical men, from which I give a few extracts in literal translation. My object is not to claim priority for Dr. Gottlieb, but to show that, starting from the same point, he arrived at conclusions differing somewhat from those reached by Dr. Clare. Dr. Gottlieb wrote:—

> "I acknowledge that the spasm of the pylorus partly causes the pains, but the principal pains are due to *the tonic spasm in the circular muscle fibres of the gastric segment, in which the ulcer is situated.* These are the muscle fibres which we see in X rays as a continuous circular spasm, usually yielding neither to atropine nor papaverine and not ceasing under the deepest anæsthesia. This spasm is, in my experience, the cause of the continual and extraordinary intense pains, localised by the patients in the epigastrium, and this is the principal impediment to the healing of the ulcer. I see in this

---

[1] THE LANCET, 1923, ii., 602.

[2] Published in Lijecnicki vijesnik, 1922, No. 2, with a French résumé. A German report appeared in the Zentralorgan für die ges. Chirurgie under the title "Zur operativen Behandlung des pylorusfernen penetr. Magengeschwürs."

continual spasmodic contraction an analogy to the blepharospasm, associated with affections of the conjunctiva or to the spasm of the sphincter at the anal fissure."

There are certain differences in the technique of the operation as used by the two surgeons. Dr. Gottlieb does not dare to make a simple gastromyotomy, because he considers it is not certain to prevent the reuniting of the divided fibres. Therefore, after having carefully divided the muscle fibres of the segment concerned, he also cuts through the mucous membrane and employs this aperture for the establishment of a gastro-enterostomy. Thereby he accomplishes the drainage of the stomach, a principle esteemed by Sir Berkeley Moynihan and others, and also secures the principle of the alkalisation of the gastric juice. Dr. Gottlieb says:—

> "Consequently, since 1916, in dealing with 320 ulcers (65 of them penetrating) I have carried out two forms of gastro-enterostomy. For pyloric ulcer or stenosis I perform gastro-enterostomy, exactly as recommended by Bier, that is to say, a retrocolic posterior gastro-enterostomy with the aperture vertical to the longitudinal axis of the stomach, and with a short jejunal loop. When operating for a penetrating ulcer, I divide the circular muscle fibres of the gastric segment on which the ulcer is located, the incision being oblique or parallel to the long axis of the stomach, and corresponding in length to the breadth of the affected segment. . . . Very frequently it is not possible to do a posterior gastro-enterostomy, as the stomach cannot be mobilised, and it is unnecessary because Braun's gastro-enterostomy leads to the same result."

I believe the technique of Clare's operation is no simpler than Gottlieb's. The isolation of muscle fibres, the care necessary to prevent button-holing the mucous membrane, the inversion and suture of the peritoneal coat surely require as much time as a gastro-enterostomy, which is done by Gottlieb—on Bier's recommendation—by simple suture, not taking longer than 20–25 minutes. In cases of large penetrating ulcers it is sometimes difficult, but always possible, to reach the margin of the segment. A similar difficulty naturally applies also to a simple gastromyotomy. A difference exists also in the indications given for the operation. Clare restricts himself to simple uncomplicated ulcers, and refuses to operate on stenosis or hour-glass contraction. Gottlieb has given up the method in the case of simple ulcers, replacing it by a partial gastrectomy. He continues to perform the operation in cases of penetrating ulcers (which now number 80). It is these which offer the greatest difficulty to resection and in which the patients are the weakest. Some years ago I had occasion to see the excellent results obtained from this operation. Pain disappeared the same day, incidentally, I take it, the best proof for the correctness of the view of its origin. Evidently Gottlieb's best results have been reached with penetrating ulcers, and may stimulate Dr. Clare to perform gastromyotomy without gastro-enterostomy on complicated ulcers.

I am, Sir, yours faithfully,

M. GROSSMANN, M.D.,
Assistant at the Medical Clinic, Zagreb, Yugoslavie.

THE FACTORY SURGEON IN INDUSTRIAL WELFARE.

To the Editor of THE LANCET.

SIR,—The excellent annotation in your issue of March 29th on the Influence of the Factory Surgeon in Industrial Welfare is much to the point. The factory medical service requires extension and supervision, and demands special study on the part of certifying surgeons. It requires to cover a later age and to include re-examination at intervals where excessive heat, moisture, dust, noise, or noxious agents are encountered; also following all conditional certificates. The Home Office medical officers, knowing the conditions of labour and their particular dangers, should inspect and supervise the certifying work of the surgeon. Lectures on industrial diseases are already given at stated intervals; these courses should be enlarged to embrace all industrial risks, especially to youth, and attendance at them made compulsory in the public health diploma course. Another important point in "certifying for fitness" is that no certificate should be given at the surgeon's office or room, but only at the works, factory, or shop, where the actual working conditions can be studied. Given under such circumstances, the certificate constitutes a child's charter of protection or security.

Personal experience warrants the statement that rejections, conditional certificates, and cautionary advice amount to between 10 and 15 per cent. of the young persons presented in certain factory departments. These young people have already received exemption from school and have been previously examined by the school or family doctor. The fact serves to emphasise the necessity of an accurate knowledge of the environment of trade processes before granting "certificates of fitness" for special work. The risks attending factory and industrial life are at present largely unknown to the medical man who is not particularly interested.

I am, Sir, yours faithfully,

Wigan, April 8th, 1924. R. PROSSER WHITE.

THE PANCREAS IN RELATION TO DIABETES MELLITUS.

To the Editor of THE LANCET.

SIR,—I was interested to read Prof. Oertel's article in your issue of April 5th on the Pancreas and Diabetic Metabolism and your annotation thereon, but was surprised to find no reference to the work of Dr. H. H. Dale (Philosophical Transactions, B, 1905), who found that in a pancreas repeatedly stimulated by injections of insulin many alveoli appeared to be converted into islet tissue. He concluded that the islets are not independent structures, but formed by certain definite changes in the arrangement and properties of ordinary secreting cells, bringing about a reversion to embryonic type. In 1908 I wrote: "After all, the nature of the islets does not really settle the question of internal secretion; . . . it does not necessarily require special cells to elaborate it. In the liver we do not find certain bile-producing cells and other glycogenic cells, but all cells seem equally concerned in both the internal and external secretions of the glands. Noel Paton points out that, while the cell-islets are well developed in the duck, the pancreas plays no part in regulating the metabolism of sugar, for excision of the pancreas does not cause glycosuria in that animal." It is interesting to see a reversion to this point of view, although the evidence in favour of the production of the internal secretion of the pancreas by the cell-islets is much stronger than when I wrote those lines.

I am, Sir, yours faithfully,

W. LANGDON BROWN.
Cavendish-square, W., April 8th, 1924.

THE WASSERMANN REACTION IN DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—Your leading article on Syphilis and the Death of the Child, and Dr. J. N. Cruickshank's letter on the Wassermann Reaction in the New-born appearing in your issues of March 22nd and 29th, respectively, afford further clear evidence regarding the limitation of the diagnostic powers of this valuable serological test.

Ever since the introduction of this serum reaction, I have urged the necessity of caution in accepting a positive Wassermann as conclusive evidence of syphilitic infection, and in a small book on the clinical pathology of syphilis and parasyphilis, published in 1912, I expressed the opinion that Wassermann's claim, "If one holds to the necessary preliminary precautions regarding the technique and anamnesis, then, in cases of a positive reaction it can be said with certainty that the investigated case is syphilitic," could not be accepted without reservation; although the test was undoubtedly a very great help to diagnosis and marked a great advance in clinical pathology.

The Lancet of May 4th, 1918, contained a note by myself on the Wassermann Reaction, its Use and Abuse, in which I reviewed various cases in which the pathological and clinical evidence appeared to be contradictory, and in which I stated, "I do not think that a positive diagnosis of syphilis can be based on this test alone, unsupported by either history, symptoms or the rapid improvement of doubtful lesions under anti-syphilitic treatment. If cases continue to be diagnosed as syphilitic on a positive Wassermann reaction alone, not only will many non-syphilitic cases be branded and treated as syphilitic, but this extremely valuable test will become discredited." The view that a positive Wassermann reaction was conclusive evidence of syphilis was then generally held, and Colonel L. W. Harrison, in his work on "The Diagnosis and Treatment of Venereal Diseases," published in that year, wrote, "excluding the above-mentioned (chiefly tropical) diseases one can say that a positive reaction justifies a diagnosis of syphilis." The Medical Research Committee in their Special Report Series concluded in No. 21 (published in June, 1918), "The percentage of positive Wassermann reactions in actual syphilis is so high that the test may for all practical purposes be looked upon as specific"; and in No. 23 (published in January, 1919), "We can, however, justly suggest that in the absence of such diseases this positive reaction is conclusive." Since that date evidence has accumulated that the Wassermann reaction, although an extremely useful test, is not pathognomonic, and this conclusion is confirmed by Dr. Cruickshank's investigation of this test in 1000 women and their new-born infants, which enables him to affirm that "a positive Wassermann reaction in a new-born infant is of no value in diagnosis" and "cannot be taken as an indication that the infant is syphilitic."

It is now established that a negative Wassermann is of little value in excluding syphilis in the absence of clinical symptoms, although when symptoms of a doubtful secondary or tertiary nature are present and the test proves negative we are justified in concluding that these lesions are probably *not* syphilitic. A negative reaction in tabes gives no help in diagnosis, but there is a strong probability that a patient giving a negative reaction is not suffering from general paralysis. It is now also established that a positive reaction does not necessarily mean that the individual is syphilitic, and so the time has almost arrived when this important serological test will take its proper and permanent place in the syndrome of symptoms on which correct diagnosis may be based.

I am, Sir, yours faithfully,
H. Wansey Bayly.

Harley-street, W., April 4th, 1924.

A CASE OF ANAPHYLAXIS.

To the Editor of The Lancet.

Sir,—Some interest attaches to a case of a woman, aged 25, admitted to the Isolation Hospital of the County Borough of Southport on Jan. 23rd. The patient was suffering on admission from extensive erysipelas, and there was a record of previous attacks. There had been two deaths in the house from erysipelas during the winter. She had marked albuminuria, and her condition was rendered more grave by the presence of pneumonia. The usual local treatment was given to the lesions and polyvalent antistreptococcic serum up to 100 c.cm. was injected. Complete recovery resulted, contrary to expectations, and patient was discharged Feb. 20th. An attempt was made to provide some lasting immunity by the administration of a sensitised vaccine (Besredka) in an ascending series, and it is a pity that the doctor who took over the case on discharge was unable to give the whole of the prepared doses. The interest is in the anaphylaxis. On March 24th the patient was re-admitted again, suffering from erysipelas, and the next day a tentative dose of two minims of the same serum was given in the skin of the forearm. On March 26th, 18 hours afterwards, a blotchy serum rash appeared, involving the skin of both fore-arms and the whole of the back. This disappeared in a day or two, and recovery from the primary condition was rapid and without incident.

I am, Sir, yours faithfully,
Southport, April 5th, 1924. G. C. Barnes.

ITALIAN LABELS ON PROPRIETARY MEDICINES.

To the Editor of The Lancet.

Sir,—The attention of this Association has been called to an article on page 256 of your issue of Feb. 2nd, headed Secret Remedies: Formulas Disclosed by the Makers, and in the course of editorial comments you suggest that these formulas are disclosed by the makers themselves.

The information that I have obtained in respect of such of the formulas quoted as belong to many members of this Association appears to show that, so far as those formulas which appeared on the labels to which you refer are concerned, they were evidently placed there by the importers for their own reasons and without the knowledge or consent of the maker. You are, of course, aware that these preparations go through many channels before they reach the consumer, and it appears to be a common practice for importers in Italy to make up a formula so as to enable them to get the goods through the Customs.

I feel sure you will appreciate these points being brought to your notice, as it is felt that your valued journal does not desire to publish information that tends to suggest that makers of well-known preparations are themselves publishing, or are responsible for any publication of, inaccurate formulas.

I am, Sir, yours faithfully,

LONDON PANEL COMMITTEE: POST-GRADUATE INSTRUCTION.

To the Editor of THE LANCET.

SIR,—Courses of post-graduate instruction have been arranged by the London Panel Committee with the assistance of the authorities of Guy's Hospital and Middlesex Hospital to commence in May. The course at Guy's Hospital will be in general medicine, and at Middlesex Hospital in the diagnosis and treatment of cancer. Each course will consist of ten lectures, those at Guy's Hospital commencing on May 1st and those at Middlesex Hospital on May 8th. The classes will be held on Thursday afternoons at 4 P.M., with the exception of one at the Middlesex Hospital, which has been altered to Wednesday, June 25th, to suit the convenience of the lecturer. The fee for each course will be £3 3*s.*, payable in advance to me, and cards of admission will be issued. Early application for inclusion in either of the above courses should be made as the numbers admitted will be limited.

I am, Sir, yours faithfully,

R. J. FARMAN,
Secretary.

51, Chancery-lane, W.C. 2. April 11th, 1924.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Rear-Admiral F. J. A. Dalton is placed on the retd. list at his own request in order to facilitate the promotion of junior officers.

Surg. Comdrs.: W. T. Maydon, to the *Calliope* (on relief); J. C. Bringan, to the *Resolution;* and F. J. Gowans to the *President*, addl., for three months' post-graduate course.

Surg. Comdr. R. H. Atkins to the *Columbine*, addl. for Naval Base at Port Edgar as Senior Medical Officer and Medical Transport Officer.

Surg. Lt.-Comdrs.: M. B. Macleod to the *Victory XI.*, for R.N. Hospl., Portland, and as specialist in ophthalmology; R. A. Brown to the *Columbine*, for R.N. Hospl., S. Queensferry, and for specialist duties.

Surg. Lt.-Comdrs. to be Surg. Comdrs.: J. A. O'Flynn, J. P. Shorten, G. V. Hobbs, F. J. D. Twigg, and G. E. D. Ellis.

Surg. Lt.-Comdrs.: C. E. Greeson to the *Barham*, and A. C. Anderson to the *Victory*, addl. for R.N. Barracks, Portsmouth, and as temporary specialist in ophthalmology.

Surg. Lt. R. W. Nesbitt to be Surg. Lt.-Comdr.

J. F. Kirwan to be Surg. Lt.

Lt. A. D. Phillips to the *Dolphin*.

ROYAL NAVAL VOLUNTEER RESERVE.

N. N. Wade, late temp. Surg. Lt., R.N., is granted an honorary commission as Surg. Lt.-Comdr. in the Royal Naval Volunteer Reserve.

ROYAL ARMY MEDICAL CORPS.

Maj. J. H. Douglass retires on ret. pay.

Temp. Capt. W. Fletcher-Barrett relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. A. J. Brown, from Gen. Hosp. List, to be Maj. (Prov.).

Capt. J. M. Milne resigns his commn. and is granted the rank of Maj.

TERRITORIAL RESERVE OF OFFICERS.

Maj. J. R. Menzies, from the Active List, to be Maj.

TERRITORIAL DECORATIONS.

The King has conferred the Territorial Decoration upon the undermentioned officers: Lt.-Cols. R. E. Bickerton, J. W. Kemp, A. A. W. Merrick, and W. A. Thompson; A. A. Ross (deceased); Majs. E. W. Herrington, A. G. Lovett-Campbell, W. A. Valentine, H. F. Wilkin, and G. T. Willan.

Mr. H. D. Gillies has had conferred on him by the King of Denmark a Commandership of the Order of Dannebrog.

Obituary.

ALEXANDER HAIG, M.D. OXF., F.R.C.P. LOND.

WITH the death of Dr. Alexander Haig last week, at the age of 71, there has passed one whose name was a familiar association with a theory in medicine to which he devoted practically all his attention. Dr. Haig's views on uric acid as a factor in the incidence of gout, rheumatism, cancer, and general conditions of ill-health were at the time of their promulgation received with a considerable amount of scepticism by the profession, nor have subsequent researches by other investigators confirmed his conclusions. Yet, although his theories have been largely discredited, nevertheless, it cannot be doubted that his clear statements and strong belief in his own work have done much to stimulate further and wider research into the causes and ætiology of many diverse conditions with which the presence of uric acid is associated.

Dr. Alexander Haig was a son of the late George Andrew Haig, of Brechin, Forfarshire, and was born in 1853. He was educated at Harrow and at Exeter College, Oxford, and received his professional training at St. Bartholomew's Hospital and at the Rotunda Hospital, Dublin, qualifying as M.R.C.S. Eng. in 1879 and M.B. Oxf. the following year, when he also graduated M.A. His first appointment was as surgeon to the Torbay Hospital, but in 1882 he returned to London where he set up in practice, and also held the appointment of casualty physician to St. Bartholomew's Hospital. Later he obtained the post of physician to the Royal Waterloo Hospital for Children and Women, and physician to the Metropolitan Hospital, to both of which he was consultant physician at the time of his death. Dr. Haig's interest in the subject of uric acid began at an early stage in his career. In 1887 he contributed a paper to the Medico-Chirurgical Transactions on the relation of a certain form of headache to the excretion of uric acid, and his thesis for his M.D., which degree he obtained from Oxford in 1888, dealt with the formation and excretion of uric acid considered with reference to gout and allied diseases. These monographs were rapidly followed by others on the rôle of uric acid in the production of disease, which appeared in various medical journals, and the columns of THE LANCET contain much that originated from him. Among the books of which he was the author are "Uric Acid as a Factor in Causation of Disease," of which the seventh edition appeared in 1908, and his "Uric Acid, an epitome of the subject" reached its second edition in 1902. "Diet and Food in Relation to Strength, Power of Endurance, Training, and Athletics" ran through six editions. In it Dr. Haig stated a clear issue. His view reduced all men and women to mere automata, illustrating this simple principle—9 oz. of albumin per pound body-weight is the art of keeping perfect health.

In appreciation of him Dr. Arthur T. Davies writes:—

"My friendship with and recollections of Dr. Haig go back many years. He was first associated with me as one of the casualty physicians (1885–87) at St. Bartholomew's Hospital and then as one of the assistant physicians (1886) to the Metropolitan Hospital in its transitional days when it was being moved from Devonshire-square, Bishopsgate, to Kingsland-road, N. Haig was a man genial in nature and of high character and integrity. He always seemed to maintain an even mental equilibrium under adverse criticism. He took the keenest interest in his work and in developing his theory on uric acid, to which he devoted an immense amount of labour and research. He was led to start his theory from observing the effects of deleting red meats on his headaches. In a letter which he wrote in 1906 to me he said: 'Of late it has come into my mind that it was perhaps a greater duty to stay at the hospital and help the poor than to make more money by giving all my time to the rich.' Commenting on the break of associations (he is referring to my resignation as physician to the hospital), he said these changes are but the first of a series in which we must eventually part from everything even life itself and the lesson surely is that there are other and better things not subject to these changes. Haig was a most kind and loyal colleague ; his motto was ‘ once a colleague always a colleague.’ ”

Dr. Haig married in 1878 Gertrude Mary, daughter of the late James Haig, barrister, of Lincoln's Inn, and had one son and one daughter.

THOMAS PARKER POWELL, L.R.C.P. & S. Edin., L.R.F.P.S. Glasg.

The sudden death of Dr. T. P. Powell of Lincoln, occurred on March 29th while he was engaged on his professional duties, and by his death Lincoln has lost a well-known local practitioner. Born in 1861, Dr. Powell was the son of the late Mr. T. Wood Powell, a Breconshire analytical chemist. Choosing medicine as his profession, he proceeded to the Royal Colleges, Edinburgh, and the Anderson College, Glasgow, obtaining the triple qualification L.R.C.P. & S. Edin., L.R.F.P.S. Glasg. in 1894. After qualifying he joined Dr. P. Thompson, of Retford, as assistant, and from there he accepted the appointment as senior medical officer to the Manchester Unity Order of Oddfellows Medical Institution, Lincoln. At that time the friendly societies' medical institutes were going through a difficult period of their history, and their relations with outside medical men were far from satisfactory. For 28 years Dr. Powell worked steadily on towards the realisation of his ambition to raise the standard of friendly society medical work. During the war he was medical officer to the Staffordshire Regiment and naval forces in Lincoln, and later a member of the Pensions Board. A man of few words and determined character, quick to take offence but equally quick to forgive, Dr. Powell held the confidence and affection not only of his patients, but of his medical brethren, by whom he is sincerely mourned.

DOUGLAS ARTHUR REID, M.D. Edin., M.R.C.S. Eng.

Dr. Douglas A. Reid, who died recently, at his residence in London, in his ninety-first year was for many years a prominent figure in the public life of Tenby, Wales. He was born at Portsea, Hampshire, and at the age of 16, in 1849, was apprenticed to Dr. James Henderson, the surgeon of Portsmouth Dockyard. A year later he entered at King's College, London, as a student, and in 1853 he proceeded to the University of Edinburgh, where he graduated as M.D. Returning to London, he passed the examination of the College of Surgeons and Apothecaries' Hall in June, 1854. Following a short residence at the Brompton Hospital for Consumption as clinical assistant, Dr. Reid entered the army as assistant surgeon at the outbreak of the Crimean War, and was gazetted to the 90th Light Infantry. Throughout the Siege of Sebastopol he was attached to that regiment and was frequently on duty in the trenches during the winter of 1855. He took part in the attack on the Redan on June 18th and in the storming of Sebastopol on Sept. 8th of the same year, and was subsequently awarded the Crimean Medal with the clasp for Sebastopol, and the Turkish Medal. In 1856 he returned to England, and leaving the service he commenced practice in Pembroke as the successor of Dr. Paynter, then the oldest practitioner in the town. In 1863 he established the Pembroke and Pembroke Dock Infirmary, and in 1866, during the cholera epidemic of that year, he was appointed by the Local Government Board as extra medical officer to the Pembroke Union to assist in coping with the epidemic. It is recorded that he had upwards of 200 cases in his charge in the course of six weeks and he succeeded in keeping the death roll below 10 per cent. In 1868 he was made a magistrate for the Borough of Pembroke, and from 1873 to 1875 was a member of the town council of the borough. From 1857 to 1874 he was a surgeon of the old Castlemartin Yeomanry Cavalry. Dr. Reid settled in Tenby in 1875, where he remained for nearly 40 years. For long a member of the town council, at the time of his death he was the senior justice of the peace for the borough. He had also been a trustee of the Tenby Charities and an Income-tax Commissioner.

For many years there were few important movements in the town in which he was not interested, and of his capabilities a correspondent writes as follows :—

“ Dr. Douglas Reid in his prime—and his prime extended to a much more advanced age than that of most men—was possessed of a boundless enthusiasm. Whatever he undertook was carried through with an energy that swept opposition off its feet, yet with an honesty of purpose that even his opponents were forced to admit and admire. He had a vivid sense of humour, a keen wit, and the power of ready repartee. Optimistic in outlook, he refused to see the dark side and the difficulties of life, and to the very end he was always seeking ‘ for some new thing,’ and some fresh cause for which to think and work. In addition to a lifelong interest in his profession, he threw himself with characteristic keenness into politics, being a whole-hearted supporter of the Conservative cause. As M.O.H. of the town in which he lived he was ever battling for the reform of abuses and the furtherance of its health and general interests, and it was owing largely to his untiring work that the first tuberculosis sanatorium in West Wales was instituted. The loss of his youngest and only surviving son, Sir Archibald Reid, early this year was a blow too severe for even his vigorous constitution, and the shock hastened his death.”

His wife died in 1912, but he is survived by three daughters, to whom we extend our sincere sympathy.

The late Dr. Q. M‘Lennan.—We regret to record the recent death of Dr. Quintin M‘Lennan at the age of 74, who for 40 years had practised in the West-end of Glasgow. He had been a visiting surgeon to the Royal Infirmary, Glasgow, and at the time of his death was the senior honorary consulting surgeon to that institution ; and he had also served on the surgical staff of the Royal Hospital for Sick Children. He was medical examiner to the Board of Trade. Dr. M‘Lennan took a great interest in the literature and music of his country.

The late Dr. A. J. Couper.—Dr. Alex. Johnston Couper, who died recently, graduated at Glasgow University in 1907, and acted for a time as a demonstrator of anatomy in the University. He then took up practice, and at the same time became attached to the surgical staff of the Royal Infirmary, Glasgow, where he was an assistant surgeon at the time of his death. During the war he served in Salonica with the Royal Army Medical Corps.

The late Dr. J. P. Williams.—The sudden death of John Prichard Williams, M.R.S.C., B.Ch., of Southgate-road, Potter's Bar, Middlesex, at the early age of 30, occurred as the result of appendicitis two weeks ago. Dr. Williams was educated at University College, Cardiff, and at Westminster Hospital, and received his medical degree in 1917. During the war he held the rank of Captain in the R.A.M.C., and from 1915 to 1917 he served with the British Expeditionary Force in Russia. Since 1920 Dr. Williams was in practice in Potter's Bar, and was a member of the honorary staff of Potter's Bar Cottage Hospital. To his widow and little daughter we extend our heartfelt sympathy.

The late Dr. J. S. Mackay.—John Sutherland Mackay, M.D., D.P.H. Ed., died in Edinburgh on March 30th, aged 77. He was the eldest son of the Manse at Lybster, Caithness, and studied at Aberdeen, Edinburgh, and St. Andrews, and after graduation took the appointment of medical officer to the Rio Tinto Copper Co., in Spain. He put the medical department of this great mine on lines which are retained to-day, conferring great benefits on the workmen and their families, for whose welfare he was an indefatigable worker. The Spanish Government recognised his labour during the cholera epidemic of 1885 by conferring on him the Cross of Isabel la Católica. After nine years in Spain he returned to Scotland, and after practising for some years in Kirkcaldy he was appointed medical officer of health for that borough. He is survived by his only daughter.

Medical Society for the Study of Venereal Diseases.—A paper on Bismuth Therapy will be read before the Society at 11, Chandos-street, W. 1, on April 25th, at 8.30 p.m., by Major A. T. Frost. A discussion will follow, in which Dr. H. H. Dale will take part, and preceding the discussion there will be a demonstration of clinical cases.

Medical News.

UNIVERSITY OF LONDON.—A lecture on the Influence of Tropical Climate on Man will be given at University College (Gower-street, W.C. 1), by Prof. Dr. C. Eijkman (professor of hygiene and microbiology in the University of Utrecht), at 5 P.M., on Friday, May 2nd. The chair will be taken by Prof. H. R. Kenwood. The lecture will be delivered in English, and admission is free.

UNIVERSITY OF LIVERPOOL.—At examinations held recently the following candidates were successful:—

DIPLOMA IN TROPICAL MEDICINE.

J. C. Carson, B. L. Chopra, M. J. Hardy, F. J. C. Johnstone, J. J. Keirans, G. Maclean, W. C. Mathur, and Elizabeth M. Theron.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on March 29th the following degrees, diploma, and licence were conferred:—

Bachelor of Medicine and Bachelor of Surgery.—Sarah B. Allan, Robert B. Allen, Alfreda M. Beadle, Derek C. Bell, Edgar F. H. Bell, Robert L. Bell, Norman Capstaff, John B. S. Guy, James A. Hislop, Walter A. Hogg, James S. Johnson, Johannes Fredericus Van Wyk Krige, John H. Laydon, Laurence V. McNabb, George M. Miller, Hector C. Reed, Sydney D. Rowlands, Gerald F. Smith, Thomas E. Stoker, Phyllis M. Walker.
Bachelor of Hygiene.—Edward T. Colville.
Diploma in Public Health (*D.P.H.*)—Edward T. Colville.
Licence in Dental Surgery (*L.D.S.*)—Leslie T. D. Heppell.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council of the College, Sir John Bland-Sutton, President, in the chair, the Jacksonian Prize for the year 1923 was awarded to Mr. Harold R. Dew (Melbourne), and a certificate of honourable mention and an honorarium were awarded to Mr. John Howell Evans. The subject of the prize for 1925 is the Pathology and Treatment of Lymphadenoma (Hodgkin's Disease).—The John Tomes Prize for 1921–23 was awarded to Mr. W. Warwick James, O.B.E., Fellow and Licentiate in Dental Surgery of the College, for his scientific work on the eruption of teeth, orthodontics, and the pathology of dental caries.—Dr. Arthur Longley Whitehead, senior ophthalmic surgeon, General Infirmary, Leeds, and Dr. Arthur Robinson, professor of anatomy, University of Edinburgh, were elected Fellows of the College, under Section 5 of the Charter of 15 Vict., relating to members of 20 years' standing.—Miss Pera Rosaline Cecilia Crawford, of the London School of Medicine for Women, was appointed Begley Student for the ensuing three years.—Mr. James Sherren, C.B.E., was elected one of the two representatives of the College on the Senate of the University of London in the vacancy occasioned by the retirement of Mr. Raymond Johnson. The diploma of M.R.C.S. was conferred upon Paul H. T. Thorlaksson, M.D. Manitoba, and the licence in dental surgery was conferred upon Jacob H. Ingel, Middlesex and Royal Dental Hospitals.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The Fellowship of Medicine programme of special courses for the months of April–May includes courses in various specialties, as well as a two weeks' intensive course at the Hampstead General Hospital in association with the North-Western Fever Hospital and Paddington Green Children's Hospital. The programme covers all departments of clinical work and a formal lecture or lecture-demonstration every afternoon. A further fortnight's course will be held at the Hospital for Diseases of the Skin, Blackfriars, from April 28th to May 10th, comprising instruction in the out-patient department and venereal cliniques. From May 5th to 31st there will be a special course in ophthalmology at the Central London Ophthalmic Hospital, consisting of clinical lecture-demonstrations dealing with subjects of interest to general practitioners. A month's course in psychological medicine has been arranged at the Maudsley Hospital, Denmark Hill, from May 5th to 30th, and will consist of lecture-demonstrations on the psychoneuroses, practical aspects of mental deficiency, &c. A course in venereal diseases will be given at the London Lock Hospitals (Dean-street and Harrow-road) from May 5th to 31st, and will include clinical work daily in the wards and out-patient departments at both hospitals with a special lecture by a member of the staff at 91, Dean-street each day. A fortnight's course will be given at the Infants Hospital from May 12th to 24th. The programme deals with infants' diseases from all sides, and consists of clinical demonstrations, "round table" consultations, lectures, &c. From May 12th to 24th a course in proctology will be held at St. Mark's Hospital for Diseases of the Rectum. The course will include operations, demonstrations, and lectures by members of the staff. Also, from May 12th to 30th an intensive course in laryngology, rhinology, and otology will be held at the Central London Throat, Nose, and Ear Hospital. Clinical demonstrations, lectures, &c., will be given each day from 9.30 A.M. to 5 P.M., and for those desiring it an operative surgery class will be arranged for. There will be a special intensive course at the Prince of Wales's General Hospital, Tottenham, from May 19th to 31st, details of which will be announced later. Copies of the syllabus of each of the foregoing courses can be obtained on application to the Secretary to the Fellowship of Medicine, at 1, Wimpole-street, W. 1.

THE King has given permission to Dr. William Hastings, O.B.E., Deputy Director-General, Egyptian Government Health Service, licence and authority to wear decorations of the Order of the Nile (second class) which have been conferred upon him by the King of Egypt in recognition of valuable services rendered by him.

MANCHESTER RADIUM INSTITUTE.—The activities of this Institute are growing rapidly. During the past year 908 in-patients were treated, and the number of attendances by out-patients was 5729. The Institute is doing research work as well as practising curative treatment, and to aid in these an assistant radiologist, Dr. G. E. Birkett, has been appointed. The deficit in the annual working account for the past year was £1734. Effort is being made to secure a steady subscription.

ANCOATS HOSPITAL, MANCHESTER.—During the year the income of the hospital and convalescent home was £23,165 and the expenditure £24,766, with a deficit on the year's working of £1600. In 1922 there were 2307 in-patients, 8937 out-patients, and 18,912 accident cases. The cost per bed occupied per annum was £131 14*s.* Dr. A. E. Barclay formally opened the new X ray department, which, with certain structural alterations, cost £2500. The resident medical and surgical staff has been increased to five.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—A post-graduate course on Diseases of the Nervous System will be held at the hospital from May 5th to June 27th. The general course will consist of clinical lectures and demonstrations, teaching in the out-patient department, and pathological lectures and demonstrations. A course of clinical demonstrations, chiefly on Methods of Examination of the Nervous System, will be given, and a course of lectures on the Anatomy and Physiology of the Nervous System will be arranged if there are sufficient applicants. Further information may be obtained from the Secretary of the Medical School of the Hospital, Queen-square, London, W.C. 1.

BANTING RESEARCH FOUNDATION.—It is proposed to raise by public subscription in Canada and the United States a sum of at least £100,000 for the purpose of establishing a Foundation in recognition of the discovery and development of insulin therapy. The purposes of the Foundation are (1) to provide further funds for the support of the Banting and Best Chair of Medical Research at the University of Toronto; (2) to establish a fund for the adequate financial support of such scientific workers as may have proposed to undertake the investigation of definite problems of medical research, for whom funds are not otherwise available. Such assistance may be given to persons working in the University of Toronto or elsewhere. The trustees for the collection and expenditure of the fund are prominent members of the University of Toronto, the medical members including Dr. W. E. Gallie, Prof. J. G. Fitzgerald, and Prof. V. E. Henderson.

ST. ANDREW'S HOSPITAL.—The eleventh annual report of St. Andrew's Hospital, Dollis Hill, N.W., shows a steady increase in the work of caring for patients who, while not suitable subjects for free treatment in charitable institutions, are unable to meet the charges necessary to secure adequate medical or surgical treatment in private nursing homes. Patients are admitted to this hospital only on the recommendation of their own medical adviser. The needs of the institution are, however, great, for, apart from the cost of maintaining an increase of free beds, there is a debt of over £1000, while the extension of the X ray department, the establishment of an electrical department, and further accommodation for the nurses and domestic staff would add to the efficiency of an institution which already fulfils a very useful purpose. During the year under notice the number of patients treated was 540, as compared with 406 in 1922. There was also a considerable increase in the number of operations performed, and the average number of patients resident in the hospital also rose by 28 per cent. The total income was £6826 and the expenditure £6988.

Donations and Bequests.—By will the late Mr. Thomas Utley, of West Didsbury, Manchester, left among other bequests £200 each to the Manchester Northern Hospital for Women and Children, the Manchester Hospital for Consumption and Diseases of the Throat, St. Mary's Hospital for Diseases of Women and Children, and the Northern Counties Hospital for Incurables.—The late Sir George Wood Rhodes, of Pont-street, S.W., who left estate of the gross value of £342,363, with net personality £336,434, left the bulk of his property, failing issue of his children, to the Manchester Royal Infirmary; the Manchester Children's Hospital, Pendlebury; the Manchester and Salford Hospital for Skin Diseases; the Manchester Royal Eye Hospital; St. Mary's Hospital, Manchester; Henshaw's Blind Asylum, Old Trafford; the Royal Blind Pensions Society; Gardner's Trust for the Blind; and to the Hospital for Sick Children, Great Ormond-street; the Queen's Hospital for Children, Hackney-road; Charing Cross Hospital; Guy's Hospital; and St. George's Hospital, London.—Under the will of the late Sir Henry Lucy ("Toby M.P.") the testator left among other bequests the income of £3000 to be divided between the Parochial Nursing Fund, the Dispensary, and the local branch of the National Lifeboat Institution at Hythe; £1000 to the Salop Infirmary, to endow a cot in the name of "Henry Lucy"; £1000 to the School for the Indigent Blind, Liverpool, to endow a "Henry Lucy" cot "in memory of my grandfather for many years master of the school"; and £1000 to the Liverpool Northern Hospital to endow a bed "in the name of my mother, Margaret Kemp Lucy." To the Westminster Hospital the testator left £1000 to endow a bed in the name of Lady Lucy, and £1000 each (payable after the death of his wife) to the following institutions: Alexandra Hospital for Children, Bloomsbury; Royal Ear Hospital; Royal Eye Hospital; Seamen's Hospital Society; Royal Hospital for Children and Women, Waterloo Bridge-road; Royal Orthopædic Hospital; Central London Throat Hospital; East London Orphan Asylum; Liverpool Infirmary for Children; Children's Convalescent Home, West Kirby, Cheshire; Ragged School Union Holiday Homes for Poor Children, London; Belgrave Hospital for Children, London; Cancer Hospital, Fulham-road, London; Charing Cross Hospital; Chelsea Hospital for Women; City of London Hospital for Diseases of the Chest; East London Hospital for Children and Dispensary for Women; Evelina Hospital for Sick Children; Guy's Hospital; Hospital for Sick Children, Great Ormond-street, London; King's College Hospital; London Hospital; Metropolitan Hospital, London; Middlesex Hospital; North-Eastern Hospital for Children, London; North London Consumption Hospital; Poplar Hospital; Royal Free Hospital, London; St. Bartholomew's Hospital; St. George's Hospital, London; St. Mary's Hospital, Paddington, London; St. Thomas's Hospital, London; West London Hospital, Hammersmith-road, London; and Victoria Hospital for Children, Chelsea, for the endowment of cots or beds in the name of "Nancy Lucy." These institutions will also participate in the residue of the property.—The late Mr. F. C. Pilkington left by will £10,000 to the Convalescent Home, Stillorgan, co. Dublin.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Wednesday, April 9th.

League of Nations Opium Conferences.

Mr. Lumley asked the Secretary of State for Foreign Affairs whether he was aware that the American Government had laid before the committee of preparation for the League of Nations Opium Conferences proposals providing that no State should rely on revenue from the production or sale of narcotic drugs except to finance the control of traffic in such narcotics; and whether it was the intention of His Majesty's Government to endorse this principle.—Mr. Ponsonby (Under-Secretary for Foreign Affairs) replied: I am informed that certain suggestions have been submitted to the committee of preparation by the United States representative for their consideration. It would be premature, and would prejudice the work of the committee, for H.M. Government to express any views with regard to these or any other proposals that may be put before the committee while they are still under the consideration of the committee.

Mr. Ayles asked the Prime Minister whether the committee appointed to prepare the agenda for the international opium conferences convened by the League of Nations had yet met; who was the British representative; and whether any statement could be made regarding the decisions taken.—Mr. R. MacDonald replied: The committee has met twice. The British representative on it is Sir Malcolm Delevingne, who represents H.M. Government on the opium advisory committee of the League of Nations. No decisions have yet been taken, but the committee will in due course submit a report to the League of Nations, by which it has been appointed.

The Spahlinger Treatment.

Mr. Smith-Carington asked the Minister of Health when the Spahlinger treatment would be available for ex-Service men who desired it.—Mr. Wheatley replied: I would refer the hon. Member to the reply which I gave on this subject on March 12th to Sir W. de Frece. When supplies of Mr. Spahlinger's remedies become available in this country it will be open to the medical officers responsible for the treatment of ex-Service men to utilise these remedies in the treatment of their patients if they consider it desirable.

Medical Reports to Board of Control.

Mr. Costello asked the Minister of Health if he would furnish particulars of the diagnosis sent in to the Lunacy Commissioners (as required by statute) within seven days after admission by the medical superintendents, in the case of the 22 sane persons mentioned in the last report of the Board of Control as having been wrongfully certified; would he procure from the Board the invalidation of the certifications and the removal of the names of these persons from the list of the certified; and would he state under what legal sanction their detention was continued for periods extending in some cases to as much as 50 days.—Mr. Wheatley replied: The Board of Control are not authorised to disclose the medical reports furnished to them by medical superintendents with regard to patients under their care. But I will supply the hon. Member with a statement showing the circumstances in which each of these cases was detained under observation. It is not possible to invalidate the certification of the persons mentioned; they were sent to the mental hospitals under proper legal authority (by order of a justice in 21 cases and by warrant of the Home Secretary in one case). Their names were, however, removed from the list of certified patients on discharge from the institutions. They were detained at the hospitals on the authority of the justices' orders and Home Secretary's warrant for periods of varying lengths to allow of special observation by the medical superintendents and further reports to the Board of Control.

Patients in Private Asylums.

Mr. Costello asked the Minister of Health what regulations, if any, had been made by the Board of Control to ensure that where no prejudicial certificate had been sent into them patients in private asylums who had not been seen by a magistrate should receive the statutory notice of their right of appeal to a judicial authority, and that when the manager of the institution had neglected his duty in this respect such neglect, which was described in the Act as a misdemeanour, should in future be followed by a prosecution of the offender.—Mr. Wheatley replied: No regulations are required, but the Board of Control have drawn the attention of the authorities of institutions receiving private patients to the requirements of Section 8 of the Lunacy Act, 1890. I do not consider that a prosecution should necessarily be undertaken in all cases of failure to observe the requirements referred to.

Mr. Costello asked the Minister of Health whether, in view of the declaration made by the Board of Control that they had been advised that neglect on the part of a medical superintendent to serve a private patient with notice of his right of appeal to a magistrate did not invalidate the reception order under which he was committed, he would take steps to enforce the right of a British subject to have his case heard and investigated by some judicial authority prior to imprisonment.—Mr. Wheatley replied: The point will no doubt be considered by the Royal Commission which it is proposed to appoint at an early date.

Danger of Proprietary and Patent Foods.

Mr. Dixey asked the Minister of Health whether he was aware of the serious danger to infant life and welfare arising from the widespread sale of proprietary and patent foods, consisting principally of starch; and whether he proposed to take any and what steps to enable local authorities to exercise control over the sale of unsuitable and unwholesome preparations advertised as infants' foods.—Mr. Wheatley replied: The matter has been the subject of investigation by my department, and I will consider what action it may be desirable and practicable to take in the direction which the hon. Member suggests.

Mr. HORE-BELISHA asked the Minister of Health what number of hours per day were worked by the asylum workers, inclusive of meal times; and whether he would arrange to bring these workers within the scope of a projected Eight Hours Bill.—Mr. WHEATLEY replied: There is no general rule, but the hours usually range from 48 to 60 per week. There is considerable difference of opinion among medical superintendents as to what hours are best for the patients and the nurses, and the subject is now under the consideration of a Departmental Committee appointed to consider the nursing service in county and borough mental hospitals, and in what directions it can be improved. I should prefer to await their report before answering the last part of the question.

Sickness Insurance Benefit.

Major EDMONDSON asked the Minister of Health whether, seeing that under the National Health Insurance Act only seven days' pay was granted for ten days' sickness, he would state why, in the case of sickness of such duration, the commencement of payment could not be dated from the first day of illness.—Mr. WHEATLEY replied: Under the Act sickness benefit is only payable from the fourth day of incapacity, but any approved society which is found on valuation to have a disposable surplus after making provision for the normal benefits to which its members are entitled, may out of such surplus provide, as an additional benefit, for the payment of sickness benefit from the first day of incapacity. Out of 6659 societies and branches in England which have a disposable surplus on the first valuation, only 66, however, elected to adopt this form of additional benefit. An increase of the weekly contribution would be necessary in order to place societies in a position to pay benefit from the first day otherwise than by recourse to their surplus funds.

After-care Colonies for Tuberculosis.

Mr. AYLES asked the Minister of Health whether he could give the number of after-care colonies for men and women who have been through sanatoria for tuberculosis now in existence; the number of cases which they had accommodated; and what the result of the establishment of such colonies had been.—Mr. WHEATLEY replied: There are at present three after-care colonies accommodating some 100 married men and their families, and 80 single men. I am aware also of two non-residential employment centres and one centre partly non-residential. I am advised that establishments of this kind must be regarded as still in the experimental stage, though the results so far obtained are hopeful.

Measles Statistics.

Mr. D. G. SOMERVILLE asked the Minister of Health the present percentage of cases of measles per thousand of the population; what was the percentage of similar cases in other countries which compiled statistics on the subject; and whether there was any explanation of the frequency of the malady in this country as compared with other countries.—Mr. WHEATLEY replied: No complete statistics are available as to the incidence of measles in this country, as the disease is no longer notifiable, except in a small number of districts, and the statistics available in regard to certain foreign countries in which the disease is notifiable do not enable me to give the figures asked for by the hon. Member. As regards the third part of the question, I may say that recent information indicates a somewhat widespread increase in the prevalence of measles in other European countries and the United States, as in this country.

Maternity Outfits.

Mr. AYLES asked the Minister of Health whether he would consider favourably any requests from health committees to be allowed to provide maternity outfits in necessitous cases.—Mr. WHEATLEY replied: I am prepared to consider any such applications.

Cost of Tuberculosis Treatment.

Mr. WILLIAM JOWITT asked the Minister of Health what was the total expenditure incurred by the Imperial Exchequer in the year 1923 upon the treatment of tuberculosis.—Mr. WHEATLEY replied: The total amount paid from the Exchequer during the financial year 1923–24 in respect of the tuberculosis schemes in England and Wales, including capital grants-in-aid of sanatoria, was £1,818,179. With regard to Scotland, a question should be addressed to the Secretary for Scotland.

Glandular Tuberculosis and Bovine Infection.

Mr. WILLIAM JOWITT asked the Minister of Health whether there were any statistics or other information available to his department to show the extent to which the prevalence of glandular tuberculosis was due to infection from bovine tuberculosis; and, if so, whether he would state the result of such statistics or information.—Mr. WHEATLEY replied: The most recent statistics on this subject of which I am aware are those published in 1922 as the result of a bacteriological examination of a number of cases of cervical gland tuberculosis undertaken on behalf of the Medical Research Council. These statistics showed that the percentage of cases due to bovine infection was highest in children under 5 years of age, and that although there was a progressive diminution in later age periods, the proportion of adult cases of bovine infection was not inconsiderable. It should, however, be stated that the number of children under 5 who were examined for the purposes of this test was comparatively small.

THURSDAY, APRIL 10TH.

Private Asylums in England.

Mr. PERCY HARRIS asked the Secretary of State for the Home Department how many asylums there were in England which were administered for private gain; the number of inmates in these asylums; and how many of the proprietors had degrees in psychological medicine.—Mr. GREENWOOD (Parliamentary Secretary to the Minister of Health) replied: There are 56 such institutions in England. On Jan. 1st, 1924, there were 170 voluntary boarders and 2797 certified patients resident. Information as to how many of the proprietors have degrees in psychological medicine is not available. My hon. friend is, no doubt, aware that the proprietors are not necessarily the licensees and need not be medical men.

FRIDAY, APRIL 11TH.

Summer Time Bill.

Sir KINGSLEY WOOD moved the second reading of the Summer Time Bill, a measure the main object of which, he said, was the permanent establishment of a six months' period of summer time from the first Sunday in April to the first Sunday in October. He claimed that opinion and propaganda in favour of permanent summer time had undoubtedly been growing during the eight years it had been in operation. This Bill would cost no money, but would rather save a great deal. He urged that it was very desirable that our own summer time should coincide with Continental summer time. Considerable objection had been raised on the ground that the health of the children would be affected. Nearly all the authorities who held that the Act was prejudicial to children took the view that this was due, not to any defect inherent in the Act itself, but to the fact that the parents did not use it rightly. On the assumption that parental control was effective the authorities responsible for the education of 4,000,000 elementary school-children would favour the Act and those responsible for only 500,000 would be against it. The British Medical Association were unanimously in favour of the proposal on the ground that it would do a great deal for the health of the community, including children.

Mr. A. HENDERSON (Cardiff), in seconding the motion for the second reading, said that he thought that the Bill would do a great deal towards increasing the sum total of happiness and enable the country to develop towards that stage when we might have an A1 nation.

Major COLFOX moved the following amendment: "That this House declines to proceed with a Bill which seeks to upset the compromise between all the interests concerned reached less than two years ago, and which would have a most prejudicial effect on the inhabitants of agricultural and mining districts."

Mr. DUFFY seconded the amendment.

Mr. R. DAVIES (Under-Secretary to the Home Office) said that this was a question for the House to decide, but in the view of the Home Office and the Government it was desirable that the Bill should be read a second time.

Mr. A. HENDERSON (Home Secretary) undertook on behalf of the Government that some of the points raised in the debate would be taken into consideration on the Committee stage.

On a division the second reading was carried by 169 votes to 129—majority, 40.

Women Medical Examiners in Criminal Cases.

The DUCHESS OF ATHOLL asked the Secretary for Scotland whether, with regard to women medical practitioners acting as medical examiners in certain criminal cases, he would state the names of the women practitioners whose services had been so utilised in Edinburgh and Glasgow, and the number of occasions since the issue of Lord Advocate Morison's letter in October, 1920, on which they had been employed in the courts of Edinburgh and Glasgow respectively.—Mr. ADAMSON replied: With regard to Glasgow, I am informed that three women medical practitioners who have been mainly employed in cases of the nature referred to are the late Dr. Mabel Jones, Dr. Elizabeth Smith, and Dr. Madeline Archibald. I regret that it is impossible to give particulars of the number of occasions on which their services have been utilised. With regard to Edinburgh, I find that owing to a misapprehension I was improperly informed when I answered the noble lady's question on Feb. 18th. I understand that in the case of post mortem inquiries the Procurator-Fiscal there has from time to time utilised the services of women practitioners, but that in cases of the kind specially mentioned in Lord Advocate Morrison's circular of October, 1920, women practitioners have not as yet been employed. I would point out, however, that, in general, in cases of assault or offence against the Criminal Law Amendment Acts it is necessary to have an immediate medical examination, which in practice has to be carried out on the instructions of the police by a police casualty surgeon. A further examination after the case is reported to the Procurator-Fiscal is rarely necessary.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Friday, April 25th.

STUDY OF DISEASE IN CHILDREN: at 5 P.M. (Cases at 4.30 P.M.)

Cases:

Dr. J. D. Rolleston: Herpes Recurrens.

Other cases will be shown.

Paper:

Dr. Forrest-Smith and Dr. Geoffrey Fildes: The X Ray Diagnosis of Pyloric and Duodenal Stenosis in Infants, to be followed by a discussion, in which Dr. Bertram Shires and others will take part.

Members of the Section of Electro-Therapeutics are specially invited to attend and to take part in the discussion.

EPIDEMIOLOGY AND STATE MEDICINE: at 8 P.M.

Paper.

Dr. Louis W. Sambon: The Elucidation of Cancer.

N.B.—It is hoped that Members of other Sections will attend this Meeting.

ELECTRO-THERAPEUTICS: at 8.30 P.M.

Paper:

Prof. Stefan Jellinek (Vienna): Some New Observations and Experiments in Electricity.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, April 25th.—8.30 P.M. A paper will be read by Major A. T. Frost on Bismuth Therapy. A discussion will follow in which Dr. H. H. Dale will take part. The discussion will be preceded by a demonstration of Clinical Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, April 21st.—College closed.

TUESDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Department.

WEDNESDAY.—2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Pernet: Skin Department. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY.—11 A.M., Dr. McDougal: Electrical Department. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 P.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily 10 A.M. to 6 P.M., Saturdays 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE. (Prince of Wales's General Hospital.)

(at 4.30 P.M.)

TUESDAY, April 22nd.—Dr. L. R. Yealland: Clinical Demonstration of Cases.

WEDNESDAY.—Dr. J. Browning Alexander: Asthma.

THURSDAY.—Mr. J. Bright Banister: Injuries Sustained in Labour.

FRIDAY.—4 P.M., Mr. J. Howell Evans: Orchitis and Epididymitis.

Appointments.

BRUCE, G. GORDON, M.B., Ch.B., L.R.C.P. Lond., F.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to Royal Aberdeen Hospital for Sick Children.

BUCKNELL, M. ASTON C., M.B., B.S. Lond., M.R.C.S., L.R.C.P., D.P.H., Bacteriologist for the City of Bradford.

FOULKES, P. G., M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for King's Lynn.

YOUNG, ROY F., M.B., B.C. Camb., Visiting Surgeon to the Western Infirmary, Glasgow.

Edinburgh Royal Infirmary: THOMPSON, MABEL, M.B., Ch.B., non-Resident House Physician; WILLIAMSON, A. B., M.B., Ch.B., BENNETT, MARGARET, E., M.B., Ch.B., non-Resident House Surgeons; MITCHELL, BETTY, M.B., Ch.B., MUNRO, J. E., MARGARET, M.B., Ch.B., and POPPER, O. O., M.B., Ch.B., Clinical Assistants.

Vacancies.

For further information refer to the advertisement columns.

Birmingham City.—Asst. M.O. £750. Also M.O. for Maternity and Child Welfare Work. £600.

Bradford City.—Asst. School M.O. £600.

Croydon County Borough.—Dental S. £600.

Gravesend Hospital.—Sen. H.S. £100.

Hemel Hempstead. West Herts Hospital.—Res. M.O. £200.

Hospital for Consumption and Dis. of Chest, Brompton, S.W.—Asst. in Dept. of Pathology. £250.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—H.P. £100.

Leicester Royal Infirmary.—Second H.P. £125.

London Lock Hospital, Dean-street and Harrow-road.—Surg. Reg.

London Temperance Hospital, Hampstead-road, N.W.—Med. Registrar. 40 guineas.

Manchester, County Mental Hospital, Prestwich.—A.M.O. £440 17s.

Mid-Wales Counties Mental Hospital, Talgarth, Breconshire.—Asst. M.O. £350.

R.A.M.C. Territorial Army.—Young Med. Practitioners.

Rochester, St. Bartholomew's Hospital.—Res. H.S. £250.

Sutton, Surrey, Downs Hospital for Children.—Second Asst. M.O., £560.

West London Hospital, Hammersmith-road, W.—Hon. Med. Reg.

Westminster Hospital.—Surg. Reg. and Med. Reg. Each £150.

Whitelands Training College, Chelsea, S.W.—M.O.

Births, Marriages, and Deaths.

BIRTHS.

MALHOTRA.—On March 15th, at Philip's Nursing Home, Lahore the wife of Captain R. C. Malhotra, I.M.S., of a daughter.

MARRIAGES.

MANN—GOULD.—On April 10th, at St. Mary's Baptist Church, Norwich, Surgeon-Commander Fairman Rackham Mann, R.N., to Hilda Mary, younger daughter of H. P. Gould, of Saxlingham, near Norwich.

DEATHS.

COCK.—On April 6th, suddenly, at Morton-crescent, Exmouth, John Cock, M.R.C.S., L.R.C.P., aged 68.

HAIG.—On April 6th, at Inverness-terrace, London, Alexander Haig, M.A. and M.D. Oxf., F.R.C.P.

JACKSON.—On April 5th, at Folkestone, Edward Jackson, L.R.C.P., M.R.C.S., late of Darlington, aged 78.

LONG.—On Wednesday, April 9th, at St. Martin's-place, Dover, John Reginald Long, M.R.C.S., L.R.C.P., D.P.H. Oxf., Barrister-at-Law, aged 53 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE LANCET: SUBSCRIPTION RATES.

INLAND	One Year	£2	2	0
	Six Months	1	1	0
	Three Months	0	10	6
ABROAD	One Year	2	10	0
	Six Months	1	5	0
	Three Months	0	12	6

Subscriptions not paid in advance are charged out at the published price of 1*s.* per copy, plus postage. Cheques and P.O.'s (crossed "Westminster Bank, Ltd., Covent Garden Branch") should be made payable to THE MANAGER, THE LANCET Offices, 423, Strand, London, W.C. 2.

For complete scale of advertisement charges apply to the Manager.

Notes, Comments, and Abstracts.

THE LIFE AND DOCTRINE OF SIR EDWIN CHADWICK.[1]

BY SIR WILLIAM JOB COLLINS, K.C.V.O., M.D., M.S., B.SC. LOND., F.R.C.S. ENG.,

CHAIRMAN OF THE CHADWICK TRUST; PRESIDENT OF THE SANITARY INSPECTORS' ASSOCIATION.

PART I.

WHEN invited by your Provost to speak at University College on Sir Edwin Chadwick, his life and work, the attractiveness of the subject chosen and the appropriateness of the *locus in quo* overcame my sense of conscious ineptitude for the graciously allotted task. As chairman, for the time being, of the Trust which bears the name of Chadwick and seeks eponomously to perpetuate his memory and his doctrine, I have dutifully attempted, on more than one occasion, to relate to audiences less august than this the story of his chequered career, whereby he earned the hatred and hostility of many of his contemporaries, the gratitude and veneration of posterity, and his final canonisation as the Father of British Sanitary Science.

As secretary to, and disciple of, Jeremy Bentham, in the later years of the utilitarian sage, Sir Edwin Chadwick, like his master, is intimately associated with this place. Bentham, for whose mortal remains your museum has been a mausoleum and whose counterfeit presentment has recently been enshrined in fresco within your dome, was one of the remarkable group of men who in the 'twenties and 'thirties of last century strove to found a University of London. The great philosopher bequeathed his library in part to this College and in part to Chadwick, while under the Trust established by the latter your professorship of hygiene has received substantial support and appropriately cherishes his memory.

Sir Edwin Chadwick belonged to the noble army of eminent Victorians, whose times and tendencies it is now the fashion to belittle and besmirch, though his early activities in association with Bentham, Grote, and the Mills, father and son, commenced some years before the accession of Queen Victoria. When that reign began, as Sir John Simon truly observes, "there existed hardly a glimmer of intelligent public interest in matters affecting the public health. The changes that came in quick succession during the following decade (1838-1848) were," according to the same eloquent chronicler of English sanitary institutions, "directly due to the zealous labours of one eminent public servant, Sir Edwin Chadwick." The younger Mill, writing in 1835, lamented at that time the aridity of English contemporary thought—"its lack of interest in the great problems of man's life and nature . . . . the nature and principles of human society and the history of philosophy of civilisation."

Even the Radical Benthamite creed, which J. S. Mill and his father did so much to promulgate, while seeking to raise the lot of the worker and urging the physical betterment of mankind, was nevertheless not deeply concerned with such metaphysical problems as the origin of life or the cognate question of the intimate pathology of contagion. Content with improving the material well-being of man as the potent panacea for all physical, mental, and moral ills, it discounted the theologians' ascription of pestilences to the intervention of the Infinitely Great, and dismissed as of small account the microscopists' assertion of the pathogenicity of the Infinitely Little. Happiness was their goal, physical well-being the means, and filth the enemy to be vanquished by personal and municipal cleanliness.

Chadwick's Part in the Rise of Sanitary Science.

The nineteenth century, which gave us Pasteur and Lister and the dawn of bacteriology, had yet earlier witnessed the birth, or perhaps one should say the *renaissance*, of sanitary science, as expounded by Chadwick and his co-workers. While laboratory investigators were claiming to identify one after another the vegetal or animal parasites proclaimed as the causes of zymotic and other diseases, the municipal engineer, the sanitary officers, local administrators, and social workers had been preaching the gospel of cleanly living, improving water-supplies and refuse removal, bettering the housing of the working classes, and claiming that to such efforts were due the reduction in the death-rate and the restriction or extinction of pestilences. These filth diseases, they said, would vanish before the application of what Chadwick had promulgated as his "sanitary idea."

Apart from minor matters, mostly of ephemeral interest, Chadwick's teaching is not without its message for us to-day. Some at any rate of our modern sanitarians and sociologists seem to lack the very qualities in which Chadwick was pre-eminent. They have not the massive grasp, the many-sided method of approach, the hold on totality which he so conspicuously possessed. The modern tendency to over-specialise, to carry on research in water-tight compartments, to hunt the little game, to restrict environment to laboratory limitations instead of ranging free o'er all the field of man, to over-accentuate the microscopic, or shall we say the ultra-microscopic, to "tithe the mint and anise and cummin," and omit the weightier matters included in, but not exhausted by, the word "environment" were no part of the moral outlook or mental outfit of Edwin Chadwick. Even Sir Benjamin Ward Richardson, who had so much in common with his hero, alike in heart and head, found Chadwick's personality defiant of ordinary classification and not easy to analyse—"he treated" he said, "all professions with equal freedom, when any subject connected with his own pursuits was under discussion; so that they who listened often wondered, when they were not intimate with him, what his own profession might be."

It was fortunate, indeed, that in the evening of his long life Chadwick found in Richardson, my old friend and colleague, a biographer after his own heart, who under his hero's eye made a worthy record of his varied beneficent activities. In 1887 Richardson published in two volumes "The Health of Nations," a review of the work of Edwin Chadwick with a biographical dissertation. Titularly, the work is reminiscent of, and perhaps conceived as a palinode upon, that other work, its predecessor by more than a century, so much talked of and so little read, "The Wealth of Nations" by Adam Smith. Each is significant of the century to which it belonged. The economics of health arrived upon the scene later than the economics of wealth, and it is perhaps the destiny of twentieth-century legislators and administrators to harmonise the competing claims of the one upon the other. Articles, reviews, reports, memoranda, blue-books flowed in rapid succession for three score years from the facile pen of Edwin Chadwick, and it is well to take down, dust, and re-peruse them, and to reflect on them in the light of twentieth-century sanitary and social science. No one can rise from that task without a vivid impression of their sanity of judgment, their modernity and presage, their large and liberal outlook, their insight and foresight, as well as of the breadth of view and the humanity of the philosophy which inspires them.

"The historian" says Richardson, "will feel no doubt that in this man some peculiar interest was embodied: that the man did some work or works which exerted a striking influence over his time, and caused great changes in its social system; and yet there will be a haze about him which will be scarcely penetrable. The man did and did not. He made laws? Yes. Was he then a legislator? No, not even a member out of office in the lower House. He did something for sanitary improvements? Yes. Was he then a doctor? No, on the contrary, he looked on them as necessary evils, and as not very likely to last." He would, indeed, have been staggered if he had lived to see the day when a State Medical Service was almost on the cards; while his amiable anticipation that "doctors were not very likely to last" was presumably based upon a too roseate expectation of the early advent of an epoch when, thanks to the realisation of his sanitary ideals, doctors would neither be able to live—nor die.

Chadwick's Early Life and Environment.

Chadwick's long life of 90 years spanned the nineteenth century with the exception of its concluding decade. He and the century were in their teens together, for he was born at Longsight, near Manchester, on Jan. 24th, 1800. His times, up-bringing and early associations combined to mould this Lancashire lad into the indomitable and indefatigable social and sanitary reformer for which occasion was so ripe. Ancestry also doubtless played its part in predestinating and fashioning this earnest apostle of "environment." From his grandfather Andrew, who lived to be 96, the friend of John Wesley, he derived, besides a title to longevity, something of the spirit of "the new philanthropy," as Green called it, which sprang from the Methodist revival, and with which the labours of John Howard, Wilberforce, and Samuel Romilly were instinct. From his father, the tutor of John Dalton, he inherited a love of natural history and philosophy, as well as a leaning towards Liberal views and literary pursuit. His mother he "lost too early for the frequent tear," and before he was ten years old he migrated with his father to London, whither the latter had been called to fill the editorial chair of the *Statesman*, a leading Liberal paper of that time.

---

[1] A lecture delivered at University College, London.

In London young Chadwick devoted himself to the study of modern languages; he attended no public school except preparatory ones at Longsight and Stockport, and entered for the Bar at the Inner Temple; but with his father's example before him, journalism claimed his early attention. While still a law student he wrote for the *Morning Herald*, the *London Review*, and the *Westminster*, then the vigorous organ of the philosophic Radicals, the Mills, father and son, and Bentham. Articles from Chadwick's pen on "Life Assurance" and "Public Charities in France" stressed the potency of environment on health, and exhibited in embryo his "sanitary idea," which afterwards germinated and developed. An essay on "Preventive Police" attracted especially the attention of Bentham, secured his patronage and friendship, and introduced him into the brilliant circle of the devoted disciples who surrounded the utilitarian philosopher in his closing years.

Bentham, who was born in 1748, three years after the death of Walpole, died the day before the Great Reform Bill of 1832 received the Royal Assent. His personality and doctrine made a deep impression on his contemporaries; his breadth of view and prodigious range of knowledge commanded the veneration and homage of his co-workers and have left their mark alike on morals and on legislation. He had been in early life the friend of Adam Smith, the Wesleys, Mirabeau, and William Pitt; later James Mill, Samuel Romilly, and Etienne Dumont were his comrades and disciples, while in the evening of his life Chadwick and Dr. Southwood Smith resided with him at his hermitage at Queen's-gate, Westminster, and acted as secretaries during the last three years of the octogenarian sage. The subsequent careers of these two notable men afforded indubitable evidence that they had been with Bentham. Southwood Smith it was who performed the quaint last rites when in strict accord with the Master's directions he delivered a funeral *éloge* over Bentham's dissected corpse in the West Street School of Anatomy, amid an awful thunderstorm. Chadwick, less acquiescent, had declined Bentham's offer of an assured income if he would become the propagandist of the utilitarian philosophy. However, besides a share of his library, the Master bequeathed him a legacy. Chadwick had no doubt acquired from Bentham a breadth of view and basic notions of a juridical system which powerfully fomented within him the forces of his developing personality. Before he was 30 he had already become possessed of, or rather possessed by, his "sanitary idea" which his sympathetic biographer Richardson thus defined or described—"It was, that man could, by getting at first principles, and by aiming at causes which affect health, mould life altogether into its natural cast, and beat what had hitherto been accepted as fate by getting behind fate itself, and suppressing the forces which led up to it at their prime source."

The Beginning of his Life's Work.

He proceeded to study typhus fever amid the rookeries of East London and nearly fell a victim to it. He became intimate with John Stuart Mill, and it is said laid unsuccessful siege to the heart and hand of his sister Harriet. Mill introduced him to Nassau William Senior, and through him in 1832 he received the appointment of Assistant Commissioner for the inquiry into the Poor-law which Lord Grey's Government had just resolved to initiate under the chairmanship of the learned and large-hearted Bishop Blomfield. From the vantage ground of this relatively subordinate position Chadwick was started on what was destined to be his life's work. Duty and faculty were united in the enterprise. All sources of information were, with alacrity, pressed into the service of the inquiry. He made investigations on the spot, he saw with his eyes and not with his ears; he indited questionnaires. His reports became models of what sanitary surveys ought to be, and statistical detail and argument formed a conspicuous element in the case he presented to the Commission to which he was later added as a member. Their report disclosed the abuses which had grown up under Acts which purported to amend, but more often had marred, the principles of Poor-law codified in the celebrated 43rd of Elizabeth (1601) c. 2, which put into statutory form what was previously common law practice. It appeared that many justices of their own sweet will ordered relief to any who applied to them independently of the parochial overseers and vestries, and later had purported to fix scales of wages according to the price of wheat and the number in family. The arbitrary law of settlement, denounced by Adam Smith and Burke, continued to tie the labourer to the soil; the burden of rates had become intolerable; pauperism had increased by leaps and bounds, and in the distressful times of the first quarter of last century some £7,000,000 a year were being squandered by 16,500 local authorities in manufacturing able-bodied paupers, without check or guidance from any central authority. The report of the Commissioners, issued in February, 1834, mainly drafted by Chadwick, though claimed by some as the work of Senior, is described by Mr. Fowler in his volume on "the Poor-law" as "perhaps the most remarkable and startling document to be found in the whole range of English, perhaps, indeed, of all, social history." It recommended the formation of a central board to control administration and to prescribe uniform regulations as to relief, while local unions of parishes were to provide workhouses, administer relief, educate and apprentice children, levy rates, appoint paid officers, and render uniform accounts, under central supervision. Relief to able-bodied paupers was to be declared illegal. The law of settlement was to be relaxed. The "principles" of that report, and of the Poor-law Amendment Act of 1834, which speedily followed it, are often referred to, but are not easily disentangled from the copious volumes of the one or the numerous sections of the other. Those principles, alike in the ideals to be aimed at and the machinery to be employed, have been endorsed by the Royal Commission on the Poor-laws which reported in 1909. That Commission reasserted the fundamental principle of the Poor-law Amendment Act of 1834 to be "that the situation of the able-bodied pauper should be, really or apparently, less eligible than that of the independent labourer of the lowest class." The epitomised version of that formula—viz., "the workhouse test"—was, however, never approved or adopted by Chadwick. As regards machinery, 16,500 parishes were consolidated into 660 unions employing some 17,000 paid officers and working under the control of a central board of three Commissioners. The eleemosynary duties of the overseers and justices passed into innocuous desuetude; wasteful expenditure was checked and rates were accordingly reduced.

Paving the Way.

The first three Commissioners, with Chadwick as their most energetic secretary, at once proceeded by rules and orders to regulate outdoor relief, to make proper classification of the infirm, the aged, the destitute, the lunatic, the children, and the vagrant, and to prescribe their respective appropriate treatment—in modern phraseology "to break up the Poor-law." In 1847 the original Commission was dissolved and replaced by a new body including ex-officio Ministers of the Crown, and thus came to be represented in Parliament. In 1849 it became the Poor-law Board, and in 1871 the Local Government Board, whose recent extinction led to the Ministry of Health in 1919.

Chadwick had, indeed, adumbrated the appointment of a Minister of Health and a Minister of Education more than 50 years ago, though it may perhaps be doubted whether he would have been altogether satisfied with those departments as we have them to-day.

The first Commissioners under the Poor-law Act of 1834 were Sir Thomas Frankland Lewis, J. G. Shaw-Lefevre, and Sir George Nicholls, who received £2000 a year each, while their secretary, Chadwick, received little more than half that sum and did more than three-quarters of the work. Lewis and Shaw-Lefevre gave tepid support only to their secretary, and Nicholls was soon despatched to Ireland. Later on Sir Francis Head and Sir George Cornwall Lewis replaced the first Commissioners and acute internal dissensions rent the Board. Lewis developed a bitter antipathy to Chadwick and in 1845 matters came to a crisis over a squabble in connexion with the Andover Workhouse. A committee, of which Disraeli was a member, was appointed to inquire into the affair by the Commons, against the wish of the Government, and reported in vindication of Chadwick and against the Commissioners, who accordingly resigned in 1847. The Press had, from the first, teemed with criticism of the Board—they were "the three Kings of Somerset House"—"the Pinch-pauper triumvirate," while Chadwick was held up to obloquy by the *Times* as "that juvenile theorist of 34—the Sucking Solon of the Benthamite creed." Other work was nevertheless soon found for his indomitable energy. Even while working on the report of the Poor-law Commission and for the Board as secretary he had undertaken other investigations. In 1833 the grim tragedy of juvenile labour in factories had, by a single vote in the Commons, been referred to a Commission, for which the earlier efforts of Sir Robert Peel, the full-blooded denunciations of Richard Oastler, and the sober arguments of Mr. Sadler had prepared the ground. Thomas Tooke, Southwood Smith, and Chadwick were the Commission, and with alacrity they inquired and reported.

Legislation, however, lingered, since the Lords resented what they described as an insidious attempt to introduce by a side-wind universal national education. The half-time system, of which Chadwick was the proud parent, the ten-hours day, the institution of Government Factory Inspectors, and the recognition that injuries of employees were a legitimate charge on an industry, may be regarded as the early or the later fruit of the Commission of 1833.

A Practical Idealist.

In 1834 a committee was appointed, amid derisive levity in the Commons, to investigate the causes of intemperance, under the chairmanship of Mr. J. Silk Buckingham. Chadwick gave evidence before it, declaring that intemperance produced pauperism, and that outdoor relief went largely to the gin-shops, the number of which was grossly excessive. He advocated the provision of playgrounds, the opening of museums and art galleries on Sundays, the encouragement of coffee taverns, and the substitution of light wines for strong alcoholic drinks. In 1838 Chadwick was one of a Commission of three to devise the establishment of a constabulary police force. His colleagues were Sir Charles Rowan and Sir Charles Shaw Lefevre, afterwards Speaker and later Lord Eversley. "Preventive Police," as I have said, had been the subject of a suggestive article by Chadwick in 1829, the year in which Sir Robert Peel's Police Act reformed the London Service and gave us "Peelers" or "Bobbies" in place of the old Charlies of the Dogberry type. Chadwick insisted upon certainty of punishment, rather than its severity, as preventive of crime. He stressed the perils of hoarding and the prudence of banking money. He preferred police to military for preventing and suppressing riots, and in a report to the Society of Arts in 1876 he urged the employment of the police in the extinction of fires. Almost his last essay was one stressing the value of the cycle in facilitating the mobility of the police.

In the first year of Queen Victoria's reign, through Chadwick's inspiration and Lord Lyndhurst's influence, civil registration of births, marriages, and deaths was enacted despite the opposition of churchmen and dissenters, who appeared to regard the reform with much the same repugnance as secular education. It was also at his suggestion that Dr. William Farr (1807-1883), the author of "Vital Statistics" in McCulloch's "British Empire," was appointed compiler of abstracts in the office of the Registrar-General. For 40 years he held that subordinate post and was eminently qualified for appointment to the higher position when it fell vacant in 1879, but political patronage decided otherwise. It is impossible to over-estimate the value and far-reaching effects of Farr's work; by accurate and comparative death-rates, general, infantile, and zymotic, he provided a standard and measure of the influence of those very sanitary measures which his friend Chadwick was so vigorously preaching and practising. The influence was world-wide, and in the language of figures Farr's work speaks in every national and local health report that sees the light to-day.

The year 1839 witnesses the registration of Chadwick's own marriage to Miss Rachel Kennedy, of Manchester; and he transferred his residence from Orme-square, Bayswater, to Stanhope-street, Hyde Park.

Sanitary Reform.

It was from the Poor-law Board of Commissioners, or rather from the brains of their indomitable secretary, that the first Sanitary Commission emanated in 1838, which led up to the great "inquiry into the sanitary condition of the labouring population of Great Britain" of 1842, with which his name is identified, and on which his reputation as a sanitary reformer largely rests. When an epidemic of fever ravaged Whitechapel and Bethnal Green in 1838 he had set Dr. James Kay and Dr. Neil Arnott to report "on the prevalence of certain physical causes of fever in the Metropolis," and Dr. Southwood Smith to investigate personally "the removal by sanitary regulations of the physical causes of sickness and mortality" in some 20 metropolitan unions. It was their reports which induced Lord John Russell to secure the issue of an order by the Queen for a larger inquiry, to cover the whole of England and Wales. The report of 1842, admittedly Chadwick's work, though not bearing his name, has become a classic in the history of British sanitary science.

Modern students of public health would find it difficult to visualise the social misery and mal-hygiene which prevailed among the masses of the people at that date. As Simon points out, when Queen Victoria came to the throne, apart from the futile Quarantine Laws, and an annual vote to the Vaccine Board, the Central Government had nothing to say in regard to the public health, and local authorities had but the most indefinite relation to it. Medicine was now summoned to the service of the State, and the engineer and architect to the aid of the municipality. The first great cholera epidemic which struck Great Britain in 1831 had caused a rude awakening, and served to draw attention to the conditions under which the poor lived and died in large urban communities. The Lords of the Council had indeed in that year issued rules and regulations similar to those drafted by Mead in 1720 and promulgated a form of prayer to be used throughout the land. They also set up provisionally a central board, vested with such sanctions as Orders in Council under the Quarantine Acts could confer, which later were hastily endorsed by temporary statutes. It was not, however, until the Chadwick régime that the potency of filth in air, water, food, soil, and surroundings became recognised in preparing the breeding-ground for epidemics, and sanitary neglect began to be denounced as the nurse, if not the parent, of contagious fevers.

Chadwick's monumental "Survey into the Sanitary Condition of the Labouring Classes of Great Britain" was the final blow to the "letting-things-alone" party in high places, and led to the institution of local medical officers of health. When he and his colleagues visited the fever-stricken homes of the poorest in our large cities, he said, "it was frequently declared by the inmates that they had never for many years witnessed the approach or presence of persons of that condition near them." "The duty of visiting loathsome abodes, amidst close atmospheres compounded of smoke and offensive odours, and everything revolting to the senses is a duty" he said, "which can only be expected to be regularly performed under much stronger motives than can commonly be imposed on honorary officers . . . The descriptions given by Howard of the worst prisons he visited in England (which, he states, were the worst he had seen in Europe) were exceeded in every wynd in Edinburgh and Glasgow inspected by Dr. Arnott and myself in company with the municipal officers of those cities. More filth, worse physical suffering, and moral disorder than Howard describes as affecting the prisoners, are to be found amongst the cellar population of the working people of Liverpool, Manchester, or Leeds, and in large portions of the metropolis." Deaths from fever and small-pox were, he found, almost exclusively confined to the worst parts of the towns. In an epidemic of the latter in Bath in 1837, which carried off over three hundred persons, scarcely a single gentleman and only two or three tradesmen were among the victims. He claimed that by knowing the general lie of a town and the conditions of its poorer dwelling houses, he could postulate the habitat and haunts of infectious diseases. He believed in the common origin of zymotics in sanitary neglect—"that small-pox follows on much the same lines as typhus, so does scarlatina, but with wider deviations as to classes of cases and conditions of persons." Sutherland and Galton, he added, had shown that in Malta plague, cholera, small-pox, and anthrax had in different years been localised in the same squalid quarters. The propagation of fever he traced largely to untrapped drains; and the use of efficient traps and glazed earthenware self-cleansing pipes was early advocated by Chadwick. He had been brought up in the belief that epidemics were largely "climatorial" in causation, but he emphasised the fact that they were "largely communicable by infection." He urged the prompt isolation of infected persons in a well-ventilated chamber, so as to "let a current of air pass through the room and over the patient; to observe all the details of regulations as to cleanliness of the patient and the articles of clothing and furniture, and the removal of excreta." He enunciated precise rules for the sanitary construction of dwellings and hospitals, laying special stress on ample cubic space to get rid of "vitiated, phthisis-producing air, and (if the crowding is intense) fever-producing air." Personal cleanliness as a prophylactic against infectious disease was also accentuated. He said, "If a great epidemic were to occur again, I would proclaim and enforce the active application of soap and water as a preventive. I have had frequent opportunities of observing this plan as a factor of sanitation," and he proceeded to cite examples.

Chadwick's Conclusions.

After a careful examination of the enormous amount of evidence which he had collected, Chadwick thus summed up his conclusion of the whole matter: "That the various forms of epidemic, endemic, and other diseases are caused or aggravated, or propagated, chiefly amongst the labouring classes by atmospheric impurities produced by decomposing animal and vegetable substances, by damp and filth, and close and overcrowded dwellings . . . That such disease, whenever its attacks are frequent, is always found in connexion with the physical circumstances above specified, and that when these circumstances are removed by drainage, proper cleansing, better ventilation, and other means of diminishing atmospheric impurity, the frequency and intensity of such disease are abated, and where the removal of the noxious agencies appears to be complete, such disease almost entirely disappears. That cases of small-pox, of typhus, and of others of the ordinary epidemic occur in the greatest proportion in common conditions of foul air, from stagnant putrefaction, from bad house drainage, from sewers of deposit, from excrement-sodden sites, from filthy street surfaces, from impure water, and from overcrowding in private houses and in public institutions. That the entire removal of such conditions by complete sanitation and by improved dwellings is the effectual preventive of diseases of these species, and of ordinary, as well as of extraordinary, epidemic visitations. That when such diseases continue to occur their spread is best prevented by the separation of the unaffected from the affected, by home treatment if possible, if not, by providing small temporary accommodation; in either case obviating the necessity of removing the sick to a distance, and the danger of aggregating epidemic cases in large hospitals, a proceeding liable to augment the death-rates during epidemics."

Chadwick saw the urgent need of a radical reform in our local government system before any real advance on the lines he desiderated could be made. He urged the unification of local government services, especially in the metropolis, and he laid it down as a "sanitary axiom that the duty of carrying fouled water *out* of houses and *out* of towns, clear of the sites, constantly through self-cleansing channels, should, with the duty of carrying water *into* houses, devolve upon one and the same authority, and that such authority should be a competent and responsible public one."

The Municipal Corporation Act of 1835 was innocent of any sanitary intention, no duties or powers in regard to housing were conferred on local authorities for another 20 years, and the country at large waited till the 'seventies for urgently needed public health legislation, although certain towns, such as Liverpool, under private Acts, had appointed medical officers of health in the 'forties of last century. It was indeed through the Poor-law and especially its Central Board that sanitary reforms were then promoted, in default of available municipal authorities, especially in rural districts.

Although Chadwick's three-volume report was published in 1842, it was not until confirmed by the Health of Towns Royal Commission in its two reports of 1844 and 1845, and after two ineffectual attempts at legislation in 1846 and 1847, that the Public Health Act of 1848 and the Nuisances Removal and Diseases Prevention Act of the same year reached the Statute-book.

In 1847, after the dissolution of the first Poor-law Board, Chadwick had been placed on a Royal Commission to inquire into the sanitary condition of London. It exposed the lack of unity in metropolitan administration, with its seven different Commissions of Sewers and 100 different paving authorities, its competitive water-supplies from unfiltered river water, purveyed by profit-earning companies on the intermittent system, its open or stagnant sewers, and innumerable cesspools.

The Public Health Act of 1848 was adoptive only, did not apply to London, and was limited in duration (unless renewed) to a period of five years, nor did it give effect to all that Chadwick desired, but it nevertheless for the time being stabilised and strengthened the General Board of Health with Earl Shaftesbury (at that time Lord Ashley) as unpaid chairman, and Chadwick, and later Southwood Smith, as its paid members. It was efficient, economical, assiduous. It applied strong action and stimuli from headquarters to lethargic local authorities and, proceeding by provisional orders rather than by private Bills, it gave umbrage to Parliamentary agents whose emoluments were thereby reduced. Walter of the *Times* renewed hostilities and opposed the metropolitan works of the Board in association with the Commission of Sewers. Hudson, the railway king, and Toulmin Smith and Joseph Hume joined in the game of baiting the Board and chastising Chadwick as the chief offender. The cry of "Centralisation" was raised, the dictatorial edicts and doctrinaire policy of the Board were denounced by the "practical men" who were content that sleeping dogs should be permitted to lie and sanitary neglect continue as ever of old. Lords Shaftesbury and Carlisle, and in the Commons Lord John Russell, endeavoured to shield Chadwick from his traducers. To him were attributed all the sinister designs of the Board against self-complacent Bumbledom and the sturdy apologists of "the wisdom of our ancestors." The wags declared that under the Chadwick régime "it was a perpetual Saturday night when Master John Bull was scrubbed and rubbed and small tooth-combed till tears ran down his cheeks, his teeth chattered and his fists were clenched with worry and pain." Matters came to a crisis in the summer of 1854, when all the disaffected interests became vocal in the Commons, and on July 31st a combined attack on the proposal to renew the Act of 1848, with its General Board of Health, resulted in the defeat of the Government by nine votes in a small House at a morning sitting.

Chadwick Deposed.

The old Board of Health was thus knocked on the head, a new Ministerial body replaced it and paved the way for variations in policy, while Chadwick at the age of 54 was relegated to private life on a pension of £1000 a year. In their final report to Lord Palmerston the Board presented their apologia, and no impartial reader of it at this distance of time can fail to appreciate the immense impetus given to sanitary reform in the quinquennium 1848-54 by Shaftesbury, Chadwick, and Southwood Smith.

Shaftesbury, in his diary, records his chagrin at "being turned off like a piece of old lumber. Such is public service! Some years hence, if we are remembered, justice may be done to us, but not in our lifetime." There was much jubilation amongst the triumphant reactionaries—they said "England wants to be clean, but not to be cleaned by Chadwick," and the *Times* wrote "Æsculapius and Chiron, in the forms of Mr. Chadwick and Dr. Southwood Smith, have been deposed and we prefer to take our chance of cholera and the rest than be bullied into health."

Sir John Simon, who became medical officer of the new Board in 1855, and who introduced a different school of thought and pathological doctrine, nevertheless writing 40 years afterwards tells how Chadwick, who merited the reformer's crown of laurels, became the best abused man of his time. He admits that he may not have been richly endowed with Pitt's sovereign virtue of patience, but he duly adds "patience under sufferings of one's own, and patience towards the sufferings of others, are not equal measures of magnanimity. Mr. Chadwick, beyond any man of his time, knew what large fresh additions of human misery were accruing day by day under the then almost universal prevalence of sanitary neglect; and the indignation which he was entitled to feel at the spectacle of so much needless human suffering, is a not ignoble excuse for such signs of over-eagerness as he may have shown . . . To him this nation unquestionably owes that our statesmen of those times were first awakened to the duty of caring for the public health, and that the first of our modern legislative endeavours were made to bring health under the protection of the Law." Simon testifies to Chadwick's "unique relations to the beginnings of British sanitary reform," and records his unfailing respect for him as "first leader in so great a cause."

(*To be concluded.*)

A SAFE LITTLE HEATING LAMP.

WE have received from Messrs. Ahlmann (London), Ltd., of 9, Phœnix-place, London, W.C. 1, a little lamp, rather larger than a pocket match-box, provided with the new solid safety fuel known as "Meta fuel," which has, we are told, been submitted to severe tests in many countries and under all sorts of conditions. It was used by the Amundsen Expedition to the North Pole and by the Mount Everest Expedition in 1922. The latter reported, "You have only to put a match to the dry, white bars or cylinders and they burn without any trouble and smokelessly, even at 23,000 feet, for not less than 40 minutes." The fuel meets the need for a small-scale combustible which can be carried about without danger of fire or explosion. It is recommended by the makers for travelling, camping out, and picnicking parties, and the lamps would certainly be useful in the nursery and sick room. Such a heater might find a place in the kit of the surgeon or bed-side pathologist. A small heater (roughly the equivalent of a 2-oz. spirit lamp) costs 7*s.* 9*d.*, packets of fuel being supplied at 1*s.* for 20 bars.

A WARNING.

To the Editor of THE LANCET.

SIR,—On March 17th a man came to this hospital and said he had met with a motor-cycle accident. He gave his name as John Bland Sutton, aged 28 years, and stated he was a medical practitioner, and a nephew of a noted London surgeon (not Sir John Bland-Sutton). In view of this he was given preferential treatment and the use of a private ward. After being under observation for 10 days it was found to be an imposture, further the man attempted to leave the hospital unobserved.

I bring this matter to your notice that other hospitals may be forewarned.

I am, Sir, yours faithfully,

E. M. PORTER,

Secretary, Nelson Hospital for Wimbledon,
April 5th, 1924. Merton, and District.

Corrigendum.—Dr. J. C. McVail writes to point out that in his article on Small-pox and Vaccination, published in last week's LANCET, a sentence in the second column of p. 769 should read: "Sanitation having taken 10 years to reduce the rate from 6 to 5·3 per cent., suddenly, in a period of weeks or months, reduced it to 1·3."

Surgeon Rear-Admiral (retd.) would like full or part-time employment, where long medical and administrative experience is needed.—Reply, Editor of THE LANCET, marked "Private."

An Address

ON

CARDIAC EFFICIENCY.

Delivered before the Sheffield Medico-Chirurgical Society

By JONATHAN MEAKINS, M.D., F.R.C.P. Edin.,
CHRISTISON PROFESSOR OF THERAPEUTICS, UNIVERSITY OF EDINBURGH.

Probably one of the most important functions of the living organism, taken as a whole, is that depending upon the cardio-vascular system. Although this in many ways is subservient to the nervous system, yet its proper function has a most important influence on the nervous regulation and in so far as life is concerned may be even the more important. Through the circulation of the blood the tissues are supplied with practically all their needs. To them the blood takes oxygen, carbohydrates, fats, amino-acids, and removes carbon dioxide and other products of metabolism. Of all the substances which the circulation supplies to the tissues the most urgently important is oxygen, for the simple reason that there is no local store of this substance, and in order that energy may be produced it must be provided in a sufficient quantity.

Factors in the Maintenance of Circulation.

The circulation of blood is maintained by the combined efficiency of the cardiac and vascular mechanisms. The heart during systole ejects into the aorta and main vascular tree a certain quantity of blood which raises the pressure to such an extent that with competency of the aortic valves and the functionating vascular system it is carried to the capillaries, where the interchange of vital substances between the blood and the cells takes place. It is therefore essential that the heart must have the capacity to eject blood at a sufficient rate to supply the tissues with their needs. Probably the most important factor in this is the regularity of the cardiac rhythm and the presence of a healthy myocardium. If arrhythmia occurs, irregular cardiac output results. But probably as important a factor in the maintenance of circulation is the presence of an efficient vascular tone. A pronounced constriction of the arterioles leads to a great increase in the cardiac work and frequently to deficiency of circulation through the capillaries. On the other hand, a very much dilated vascular periphery may diminish the pressure in the general vascular system and contribute to a gross diminution in the volume of blood returning to the heart for further circulation.

In order that the needs of the organism may be supplied under great variations of rest and work functional flexibility of the circulation is necessary. Therefore the heart and vascular system must have a considerable power of reserve. If it be taken that the cardiac output per beat is constant, an increased circulation is only possible by an increase of the rate of the cardiac systole. If, on the other hand, it be taken that the resting or basal systolic output is not the maximum, but with an increased demand the systolic output is larger than at rest, the same increase of rate would not be necessary. It has been found that in certain apparently normal individuals the increase of rate is the main factor in increasing the amount of blood circulated per minute.[2] In others there is not only an increased rate, but also an increased output per systole.[1] In the former it has been found that they have a greater capacity of oxygen utilisation,[2] and, therefore, that the tissues can perform their functions with a lower partial pressure of oxygen in the capillary blood. This, however, does not necessarily indicate that at rest the systolic contraction is incomplete in either of these respects. It might probably indicate that the diastolic relaxation in some is greater than in others.

Effect of Increased Work on Size of Normal Heart.

It has been debated as to what occurs in regard to the size of the normal heart on increased work. It has been demonstrated[3 4] that in individuals with a relatively great power for work (whether it be required through an increased demand or through the heart labouring under disadvantageous circumstances, such as high altitudes) the cardiac outline becomes definitely smaller under such demands, while in those with a relative physical debility the shadow does not decrease appreciably. The question now arises as to whether this orthodiagraphic area is indicative of the size of the heart during systole or diastole. To those who are accustomed to estimate the cardiac shadow it is quite apparent that the area which is most obvious, either by ortho-diagraphic means or X ray, is the average area which occurs with complete systole. The diastolic area is very hazy and is only determined with great difficulty and inexactitude. It may therefore be concluded that the heart at the end of complete systole is smaller than usual in those individuals who are capable of performing heavy muscular work, either under normal or abnormal circumstances. It cannot, however, be presumed that this would necessitate a relatively greater capacity at complete diastole. The question therefore resolves itself into a discussion as to whether increased cardiac efficiency is accomplished by an increased systolic output and an increase of rate or by an increase of rate alone. As yet there is not sufficient data to decide this point in so far as the average normal person is concerned.

It has been shown in the normal individual that there is a direct relationship between the minute volume of the circulation and the general oxygen consumption per minute. Although this ratio may not necessarily be the same in different individuals, it maintains a more or less definite relation in the same person from time to time, other conditions being equal.

Cardiac Inefficiency.

Cardio-vascular deficiency may be said to develop when through circulatory disturbances an adequate supply of oxygen is not supplied in proportion to the needs of the organism. This in the first instance may be due not directly to a cardiac inefficiency, but to a great decrease in the vascular tone. The first and a very early effect in such cases will be a deficient return of blood to the heart, irrespective of the cardiac output. The end-result, however, will be the same as that resulting from failure of cardiac output. Whether the deficiency begins in the heart itself or in the vascular system, the first defect which the system feels is a deficiency of an adequate supply of oxygen. It will make a more concrete picture if we consider the question of cardiac function irrespective of the disturbance of vascular tone. The causes of cardiac inefficiency may be broadly divided into three classes—namely, (1) valvular lesions, (2) myocardial inefficiencies, (3) rhythmic disturbances.

1. *Valvular Lesions.*—The valvular lesions may be divided into two broad classes—those which interfere with the free onward propulsion of the blood-stream and those which allow of a certain amount of regurgitation. The conditions in the right heart which lead to either of these are either congenital in origin or are secondary lesions of the left heart. In so far as regurgitations are concerned, unless they be rather gross, an efficient myocardium may accommodate itself by hypertrophy and enlargement of the cavities to overcome the deficiency which results from such regurgitation of blood from either the aorta into the left ventricle or from the left ventricle into the auricle. Individuals suffering from such a lesion may be able to accomplish considerable work without any untoward symptoms. On the other hand, an interference with the onward flow of blood caused by a stenosis of either the mitral or the aortic orifices may lead to considerable physical incapacity. The cases of uncomplicated aortic stenosis are so rare that as yet no observations are

available. It might be supposed that in mitral stenosis the flow of blood from the auricle to the ventricle, both during systole and diastole, would be grossly impeded. The ratio between the amount of blood which enters the ventricle during diastole and that which is expelled during the auricular systole is not known. On taking the capacity of the two cavities into consideration it would be suggested that a considerable amount of blood flows into the ventricle during the diastole. This normal flow would probably be impeded by a mitral stenosis in proportion to the degree of the narrowing. In addition the auricle during its systole would likewise be handicapped in emptying its contents in a forward direction. The end-result would probably be a decreased flow of blood from the auricle to the ventricle in each cardiac cycle. This is corroborated by the manner in which the ventricle hypertrophies, although its cavity becomes smaller. The final proof is found in the fact that the output per systole in cases of mitral stenosis is conspicuously below the normal amount.[5] This decrease of the ventricular output may be so great as to necessitate, even at rest, an increase in the cardiac rhythm. It would appear that the normal resting individual has a greater circulation-rate than the needs of the moment require. This reserve is apparently provided to meet the immediate but comparatively slight demands which the ordinary movements of quiet life require. In the cases of mitral stenosis, however, where this reserve is being constantly used or exceeded, the slightest increase of work demands an increase of circulation relatively much greater than in the normal person. Therefore, the cardiac-rate must immediately and abnormally increase. The ventricular output per beat would most probably remain constant, and there is evidence which suggests that it may become smaller.

2. *Myocardial Deficiency.*—Of much more importance than the mechanical interference which valvular lesions may afford to the healthy myocardium is the question of myocardial efficiency. Any condition which interferes with the proper blood-supply to the myocardium or contributes to a degeneration of the muscle would probably produce a deficiency of circulation. A proper blood-supply may not be available for two reasons. In the first place it may be that the quality of the blood is abnormal, but normal in quantity, or secondly, that a normal quality of blood is deficient in quantity. In the first instance the arterial blood may be deficient in oxygen, as occurs in pneumonia, coal-gas poisoning, laryngeal obstruction, emphysema, anæmia, &c. This condition is especially harmful if it be produced acutely. In such cases one of the most essential constituents of the blood is deficient, and as a consequence the myocardium is greatly handicapped in performing its work. If this abnormal condition of affairs persists signs of cardio-vascular failure will develop, as it seems impossible for the myocardium to continue to functionate adequately without a generous supply of oxygen. As myocardial failure develops on account of the poor quality of the blood the quantity of the blood circulated will also become less and so a vicious circle will be established. This must be remedied by increasing the oxygen saturation of the arterial blood or else fatal cardiac failure will ensue. Secondly, if for any reason the vascular supply to the myocardium be interfered with—either through decrease in aortic pressure preventing the coronary arteries from acquiring their full pressure of blood, or through a stenosis or obliteration of the coronary orifices or the main branches—signs of cardiac embarrassment will be evident. If this deficiency of blood-supply primarily affects the myocardium and not the other tissues as well, the first signs of interference with function will be referred to the heart alone, and will be manifested by the characteristic syndrome commonly called angina pectoris. It must be recognised, however, that there is a relationship between the amount of cardiac work demanded by the organism and that which the heart may accomplish without alarmingly exceeding its own maximum blood-supply.

3. *Rhythmic Disturbances.*—When there are gross disturbances of cardiac rhythm, such as paroxysmal tachycardia and auricular flutter and fibrillation, a conspicuous decrease in the circulation-rate per minute occurs. In paroxysmal tachycardia where there is a complete auricular systole corresponding to each abnormal and rapid auricular excitation wave, it has been shown by Barcroft and his colleagues[6] that there is a very prompt and conspicuous fall in the circulation-rate per minute. This may probably be accounted for by the decrease in the period of auricular diastole, and by a compensatory protection on the part of the peripheral circulation. However, the exact mechanism of this decrease is not as yet quite clear. In auricular flutter, on the other hand, where there is apparently no complete auricular systole, and the ventricle is supplied with blood only during its own diastole, through a matter of gravity, the ventricular output will depend upon the amount which enters the ventricle during such a period. If the ventricular rate be 150 per minute, the period of systole will amount to 45 seconds and the period of diastole to 15 seconds; therefore, out of every minute the ventricle can only be filled with blood during 15 seconds. If, on the other hand, the ventricular rate be 75 per minute the period of systole will only occupy 22·5 seconds, and consequently during 37·5 seconds the ventricle will be filling with blood.* Under such circumstances the minute output of the ventricle would be conspicuously increased, in fact would practically return to the normal resting volume. On exercise, however, the rate would be apt to increase immediately to 150 per minute. There would be some gradation according to the peripheral demand, and as the auricle does not empty itself completely the circulation-rate would again depend upon the period of ventricular diastolic relaxation. A similar state of affairs occurs in auricular fibrillation, although in this condition the various factors are accentuated. It is a well-known fact that muscular activity is much more efficient if it occurs in a definite and regularly rhythmic fashion. In auricular fibrillation with a rapid ventricular-rate this is known not to occur. The ventricle may contract many times without an adequate blood-content, and the rate under such conditions affords no indication as to the volume of the circulation-rate; in fact, it may be taken to be an inverse ratio. In all of these conditions of rapid ventricular action due to abnormal excitation, the myocardium as well as the general organism suffers from a deficient circulation, and furthermore, the delicate gradation between demand and supply is completely upset. In cases of bradycardia, such as those due to complete heart-block, which are, as a rule, associated with a myocardial lesion, the cardiac output per minute, provided that there is no valvular or serious myocardial lesion, would be quite adequate for the resting organism. If, however, on account of exertion there be a demand for an increased blood-supply by the general organism, the ventricle being unable to increase its rate beyond its inherent rhythm, an augmented blood-flow could not be provided, except by increasing the output per beat. However, it seems apparent from the investigations which have been made up to date that the blood-supply under resting conditions in cases of heart-block is greater than required, and as this lesion, as a rule, occurs in elderly people where the demand for an increased blood-supply is limited on account of their diminished capacity for work, the deleterious results are not so obvious as in younger people.

Symptoms of Impaired Cardio-vascular Function.

The symptoms of impaired cardio-vascular function are very diverse. If the lesion primarily produces a deficiency of blood-supply to the myocardium, or if the myocardium be grossly damaged through bacterial or other intoxication, the symptoms will centre about this organ. The functional effect of such lesions may vary greatly. In those cases where there is a pronounced interference with the myocardial circulation, very incapacitating symptoms develop, and sudden death may ensue. On the other hand, when the cardiac debility is the result of a myocardial intoxication, limitation of effort is much more graded, and the individual is warned to circumscribe his effort, before serious myocardial embarrassment occurs.

---

* These times are only approximate.

The quantity and quality of the blood-supply and the condition of the myocardium must be considered with reference to the amount of work which may be demanded at the moment. For example, in an individual aged 45 with coronary sclerosis and deficiency of myocardial blood-supply, the amount of work which they would expect to accomplish in an ordinary existence may be much in excess of that which the myocardium is in a position to accommodate. If such individuals rigidly restrict their effort they may continue without any symptoms, and after 10–20 years, when their general capacity for physical exertion is decreased, they may be able to do all the efforts ordinary to their age without symptoms. In other words, their condition has been reduced to a simple equation between demand and supply. If the demand be small enough, and the supply adequate, then the individual will be free of symptoms. If, however, there is a progressive decrease in the demand in proportion to a progressive decrease in the supply, the relationship will remain unchanged.

The acute cardiac symptoms occur in their most aggravated form as a result of diminished vascular supply to the myocardium. But they may also appear with scarcely less acuteness if the cardiac muscle be degenerated from other causes, from a bacterial invasion as in rheumatic fever, or from a specific toxin, as in diphtheria. It must be realised, however, that in all these latter conditions the general muscular and glandular system may also suffer, and, therefore, the general fitness for exertion may be conspicuously diminished. Under these circumstances the same urgency for an increased blood-supply may not be operative. This is well exemplified in cases of pronounced anæmia. Not only is the oxygen-supply to the myocardium diminished, but there is an oxygen-want in muscles, glands, and central nervous system. Therefore, when the individual attempts any physical or mental exertion the tissues supplied by the peripheral circulation suffer first, and as the myocardium is the primary recipient of an adequate blood-supply, provided the coronary system is normal, the symptoms are usually apparent in the periphery before cardiac distress is evident. Likewise, in those cases where the blood-supply to the myocardium is comparatively efficient, but the general circulation is impaired due to a diminished circulation-rate per minute, signs of peripheral disturbance are first obvious. These will primarily occur on exertion. One of the most important is dyspnœa. As the general blood-supply is deficient, the circulation through the periphery becomes decreased. There is therefore a local decrease in the partial pressure of oxygen and a relative increase in the carbon dioxide and other products of metabolism. Such a condition of affairs will have a distinctly disturbing effect upon the peripheral tissues. Those which require the greatest supply of oxygen will suffer first, as, for instance, the central nervous system, and the respiratory centre will probably manifest the first symptoms of distress. The result will be an increased pulmonary ventilation which will bring about a lowering of the carbon dioxide content of the arterial blood, and an attempt to increase the oxygen saturation. If in spite of the symptoms the effort be carried further, fatigue, exhaustion, and even unconsciousness may result. It is quite obvious that these developments are merely comparative, as it is common knowledge that the best of athletes, if they push their physical endeavour beyond their circulatory capacity, may develop syncope.

WIDENING RANGE OF CIRCULATORY IMPAIRMENT.

If the circulatory inefficiency be so extreme as to be manifest even at rest, more widespread and obvious symptoms develop. There is evidence to indicate that the more important parts of the organisms, such as the central nervous system, the kidneys, the liver, and the gastro-intestinal tract, are so placed that they may obtain an adequate blood-supply to the detriment of the skeletal structures. Therefore, when the body is completely at rest these systems may carry on their work without obvious symptoms, while the subcutaneous tissues and the muscles, particularly in the dependent parts of the body, may be very inadequately supplied with blood, and the circulation-rate through them be reduced to the lowest limit. As a result local asphyxia occurs in the most peripheral structures. As the decrease in circulation-rate progresses, the range of this circulatory impairment increases, and eventually the kidneys manifest their lack of adequate blood- and oxygen-supply by decreased function, as shown by a diminished flow of urine. In the meantime the circulation through the lungs may become so slowed that exudate of fluid occurs. This now produces a vicious circle. Such exudate or œdema interferes with the oxygenation of the arterial blood, which in turn reduces the supply of oxygen to the vital organs. As a consequence there develops a further and progressive decrease in the efficiency of the myocardium and the function of the other organs even at rest, with the occurrence of dyspnœa and orthopnœa, gastric distress, &c.

It has often seemed a paradox that as the cardiac dullness enlarges the evidence of circulatory failure may increase. We have found in these cases that there is a decreased circulation and also a conspicuous decrease in the output of the heart per beat in spite of the enlargement of the cardiac area. This can only be explained on the presumption that although the capacity of the ventricle is increased the completeness of the ventricular systolic contraction is diminished. Therefore, although the capacity of the left ventricle may be 150 c.cm. the systolic contraction may expel only 40 or 50 c.cm., thus leaving a residue of some 100 or 110 c.cm. of blood in the ventricular cavity.

We have further been able to demonstrate that if a relatively excessive demand for cardiac work be persisted in, the cardiac area may either remain in this dilated condition or may still further increase, and the systolic output progressively become less. This will occur whether the myocardium be the site of a chronic degenerative lesion or be suffering from an acute infection as so frequently occurs in acute rheumatic fever.

Increased Demand and Progressive Decrease of Functional Power.

There would appear to be a general law applicable to all functionating tissues of the body. It may be briefly stated as follows: if an organ be performing its work with difficulty, a gradual deterioration will occur if this increased demand be persisted in. On the contrary, if the work demanded of a diseased organ be less than its capacity at the moment a certain degree of restoration of function will ensue. This is exemplified in the recovery of function by the islands of Langerhans in diabetes mellitus if they be given a rest through decreasing of carbohydrate in the food, and also in cases of locomotor ataxia, when, after a period of physical rest, re-education may be undertaken, provided fatigue be not induced. If, however, an increased demand be continued, a progressive decrease in functional power will be evident.

This, therefore, points to one of the cardinal principles in the treatment of cardiac deficiency. When the myocardium is suffering from any abnormal blood-supply or mechanical handicap, and shows signs of failing under the burden, it should be placed as near as possible in an absolutely resting condition, in order that it may have an opportunity of regaining some of its lost reserve.

I would like to take this opportunity to plead for a more organised and systematic handling of acute cardiac disease in children. If we cannot as yet prevent its occurrence, can we not do more to investigate the disabilities which handicap these little sufferers from the very threshold of their lives? I am convinced that much can be done to prevent the progress of functional deterioration in this crippling and fatal disease.

Lumleian Lectures

ON THE CLINICAL FEATURES OF FOREIGN BODIES IN THE BRONCHI.

Delivered before the Royal College of Physicians of London

BY THOMAS McCRAE, M.D., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

LECTURE III.

Delivered on April 10th, 1924.

DIAGNOSIS.

THE first essential is a knowledge of the condition which should be considered in every case of respiratory tract disease which shows unusual features and, one may add, in some cases which seem to show no unusual features. So long as we regard a foreign body in the trachea or in a bronchus as a curiosity which is not likely to come under personal observation the diagnosis is not likely to be made. The *history* is most important if there is anything in it to suggest the possibility of a foreign body, but no weight should be given to a negative history. It is pathetic to find how often the patient suggested the possibility of something having gained entrance to the respiratory tract, only to have ridicule cast on the idea or to be told that it was impossible. Children have insisted that they had "swallowed" an object only to be laughed at. In some cases many years later the truth of the statement was proved. It is a common happening to choke when eating or drinking and nothing much is thought of it. The aspiration of a foreign body may cause nothing more and the disturbance may be so slight that no attention is given to it. Unless the distress is very severe a child is not likely to report it. It is surprising in the histories to find how often it was known that an object had been in the mouth and disappeared. The usual course of events is to infer that it was swallowed, and even if the stools were examined and nothing found, the incident is regarded as closed. How this can be done when the object which disappeared was an intubation tube, a tack, a staple, or a paper fastener is difficult to understand. Some people must have a great deal of the desire to hope for the best under all circumstances.

The *symptomless interval*, perhaps after some initial symptoms, which is common with inorganic foreign bodies, has played a large part in the errors in diagnosis. It may persist for days, weeks, or months, and the later symptoms are not regarded as having any association with the suspicious symptoms at the time of aspiration. The cases in which a tooth gained entrance while the patient was under anæsthesia offer a good example. The patient may make no complaint after coming out of the anæsthetic, and a cough, perhaps slight, is not regarded as of any special significance.

The occurrence of acute features, such as chills and fever with a rapid pulse and respiration-rate, often leads to a diagnosis of "influenza" or pneumonia, or perhaps, if they are not severe, to a diagnosis of bronchitis. It is remarkable how often the diagnosis of "pneumonia" appears in the histories. In the more chronic conditions if a lower lobe bronchus is obstructed the diagnosis of empyema is frequent. Pulmonary tuberculosis has been a common diagnosis, although one would suppose that the absence of tubercle bacilli might arouse doubt as to its correctness. It is interesting to note that pulmonary tuberculosis was found in only one of Dr. Jackson's patients with a foreign body in the air passages. If abscess or bronchiectasis has resulted these may be recognised, but the causal factor is not determined.

We have seen an interesting development as a result of the increased knowledge of bronchial foreign bodies—namely, that more and more suspicious cases are being sent to the clinic. Many of them present very difficult problems and require a period of observation before an opinion can be given. In the majority there is a possibility that a small piece of a nut may have been aspirated. A very small portion of a nut may excite inflammation but may not give sufficient signs to justify an immediate diagnosis. Fortunately, in these cases the size of the particle is such that there is no extensive blocking, and in the majority it seems to be expelled with the secretions sooner or later.

These doubtful problems are usually found in young children, and a common history is that the child while eating nuts suddenly choked and coughed. Following this there may be some cough and probably fever. The child does not seem very ill and the physical signs are about as follows. There is decreased expansion on one side, usually in the lower thorax, which may not be very marked. In the lower axilla of the affected side there is slight dullness, and on auscultation the breath sounds are distant with perhaps a few râles. The X ray study may not show any decided change in the lung, or the shadow of the lower part of the lung may have a slightly increased density. These signs may persist for some weeks and gradually disappear. Our inference in these cases is that a small particle has gained entrance to the bronchus and set up a local inflammation. With increase in secretion and the expulsion of this by vigorous coughing the foreign material is usually expelled. In some cases there may be a number of small particles. One point of interest in these cases is that the dullness is in the lower axilla and not in the lower back as a rule. In none of these cases has the question of pneumonia caused any difficulty.

It is best to discuss the diagnosis of certain groups, the members of which show considerable similarity. The need of frequent examinations in puzzling cases must be mentioned again. The signs are often so variable that much aid comes from this fact, especially in the diagnosis from pneumonia and empyema. In the cases in which the signs are definite and remain unchanged there is rarely much doubt.

Acute Cases.

These are usually due to foreign bodies of a vegetable nature, such as a nut, pea, or bean, and the clinical picture produced is distinctive to a considerable degree. Prompt diagnosis is usually necessary to save life. Emphasis must be laid on the severe character of the symptoms. The children are often desperately ill with high fever (often 104° to 106° F.), a rapid pulse-rate (140 to 180), a rapid respiration-rate (40 to 80), and evidence of marked toxæmia. In the more severe cases the dyspnœa is extreme, with marked cyanosis, and the struggle for breath is pitiful to witness. In some cases the toxæmia is so marked that the child makes little or no effort to cough. In milder cases the distress is less but any movement or exertion brings on severe dyspnœa, strangling cough, and cyanosis. If there is marked secretion, as is the rule, there may be great difficulty in bringing it up and frequent ineffectual paroxysms of cough occur. This picture is that of one drowning in his own secretions. The picture may be of maximum severity with the foreign body in the trachea or in a bronchus. In either case the intense tracheo-bronchitis, which is excited and appears so quickly, probably has more to do with the symptoms than the mechanical effects of the foreign body unless it is in the trachea.

There is often the picture of *obstructive emphysema*, which is very deceptive when first seen, so much so that it is easy to mistake the side which is involved. With the lung over-distended with air, that side of the thorax is full but shows no movement, in strong contrast to the other side which shows an extreme degree of movement. The percussion note shows varying degrees of hyper-resonance or tympany, and if the condition has existed for some days there is usually some dullness below, especially in the axilla and adjoining back, probably due largely to secretion. The heart is moved towards the unaffected side. If the foreign body blocks one lobe only—usually a lower lobe or the right lower and middle lobes—the signs are less general; with a longer duration the air is absorbed, varying degrees of collapse occur, or the lung becomes filled with secretion.

The diseases for which this condition is most likely to be mistaken are diphtheria and pneumonia. The former error is shown by the number of patients who come with a history of diphtheria antitoxin having being administered. A large proportion of all foreign body cases—and especially those with vegetable foreign bodies—come with a *history* of a diagnosis of pneumonia and often of repeated attacks. It may be said that the writer has not seen an instance of lobar or broncho-pneumonia with a foreign body, and in no case has the diagnosis of pneumonia had to be seriously considered. No doubt the two might occur together, and probably some day such a case will be seen, but so far the coincidence has not been observed. In some cases there are multiple small areas of "septic" pneumonia found at autopsy, but these are not recognisable clinically and do not come under the clinical designation of lobar or broncho-pneumonia. We might expect that broncho-pneumonia would be common when we consider that the bronchi contain large amounts of pus, sometimes for long periods of time. May it be that in the ætiology of broncho-pneumonia we have given too much weight to the factor of infection by the bronchial route? The study of the foreign body patients suggests that we have.

Diphtheria.—Even with a suspicious foreign body history this diagnosis is often made. The toxæmia and the features of laryngeal obstruction, often present with a foreign body, suggest diphtheria. The fever is usually higher in foreign body cases—104° and 105° being common—than in diphtheria. Direct laryngoscopy is indicated and should prevent error. The result of cultures is important. As there are usually signs in the chest suggestive of a foreign body the finding of them throws doubt on the diagnosis of diphtheria.

Pneumonia.—The distress, dyspnœa, cyanosis, high fever, rapid pulse, and respiration-rate all suggest this. If the examination consists largely in the use of the stethoscope the presence of rough breath sounds and râles may seem to support the diagnosis. But a careful study of the physical signs should prevent error, certainly in the great majority of cases. If there are local signs suggestive of foreign body but doubt remains, the X ray should answer the question. The greatest difficulty arises in the cases of a foreign body in the trachea in which there are harsh breath sounds with many râles over both lungs and some dullness in the lower part of both lower lobes, probably due to the accumulation of secretion. The breath sounds in these cases do not suggest pneumonia, and the râles are usually very coarse and of a kind not usual in pneumonia. One source of difficulty is a restless, frightened child in whom examination is difficult at first. Patience and repeated examinations may be necessary. The frequent change of signs in a short interval is often of value. If the signs in pneumonia are marked there is rarely any question of the diagnosis. If the signs in a foreign body case are general, this may be due to a body in the trachea, in which event they are largely found on auscultation. If due to a foreign body in a bronchus, the general signs are due to bronchitis and secretion, while the lung involved gives characteristic local signs.

The X Ray Diagnosis of Non-opaque Foreign Bodies.

The majority of the cases with acute features are due to non-opaque substances, usually vegetable, and therefore the X ray diagnosis must be made by a study of the changes in the lungs. As regards the diagnosis from physical signs, it makes no difference whether the body is opaque or non-opaque, but from the X ray side the problem is a much more difficult one. By systematic study of these cases, however, Dr. W. F. Manges, of the Jefferson Clinic, is able to diagnose the presence of the non-opaque about as accurately as the opaque substances. The changes in the group of cases in which a ball-valve action occurs are especially characteristic, for if air enters the lung but cannot escape there is *obstructive* emphysema on the *affected* side and *compensatory* emphysema on the *unaffected* side. This was first described by Iglauer [1] in 1911 and 1912 and has been extensively studied by Manges.[2] The signs of acute unilateral obstructive emphysema are: (1) Greater transparency of the affected side, due to the larger amount of contained air; (2) displacement of the heart and mediastinal structures towards the unaffected side, due to the greater size of the affected lung; (3) depression and partial fixation of the diaphragm on the affected side; (4) compensatory emphysema on the unaffected side with increased excursion of the diaphragm. The movement of the sound lung is marked and hence, in plates taken at full inspiration, there may not be much difference in the shadow of the two lungs, but at the end of expiration the plate shows a marked difference. The changes are most marked at the end of expiration. The diaphragm signs are most important and enable obstructive to be distinguished from compensatory emphysema if there is any doubt. The signs are most marked if the child cries or struggles. The picture seen by the fluoroscope is striking. (Fig. 7 on Special Plate, THE LANCET, April 19th.)

This condition may persist for some time if nothing occurs to prevent the entrance of air. With swelling of the mucosa the entrance of air may be prevented at times and so the signs may vary. Air may be absorbed and secretions accumulate. After complete removal of the foreign body these signs usually disappear within a few hours. If they persist after 24 hours there is probably another foreign body present, which is not uncommon in the case of nuts, several fragments of which may have been aspirated.

Secretions may accumulate in the portion of lung below the foreign body and give an increased shadow. This may be difficult to distinguish from the early stages of abscess. *Collapse of the lung*, if marked, gives definite signs. The heart is displaced to the affected side, the position of the diaphragm is high, and there is a marked shadow over the area involved. If a foreign body in the trachea causes considerable obstruction there are signs of obstructive emphysema in both lungs. The diaphragm is depressed on both sides and is higher on inspiration than on expiration; the heart is vertical and more in the mid-line.

Inorganic Foreign Bodies which Do Not Cause Complete Obstruction.

1. There is a variable *history*—if one can be obtained—of choking and gagging at the time of entrance followed by a symptomless interval of variable duration.

---

[1] Ohio Medical Journal, April, 1911, and Lancet-Clinic, 1912, cii., 22.

[2] Amer. Jour. of Roentgenology, 1922, xii., 288.

2. The amount of *cough* varies, but tolerance is soon established as a rule. The cough, which appears later, is due to the secretions and the irritation caused by them. Should the foreign body remain in the trachea cough is likely to be a marked feature.

3. *Sputum.*—This may be blood-streaked early and consist largely of mucoid material. Later it tends to become purulent and very often foul and offensive. A varying length of time elapses before this occurs. With abscess formation and the establishment of bronchiectasis the sputum is of the usual character found in these conditions. Hæmoptysis is not uncommon, and some histories speak of it occurring at intervals over many years.

4. *Fever.*—This is present at some time or other. In the early stages it may be present for a few days and then disappear to return later. The height and character of the curve are very different; all varieties are seen. With suppuration the record is that usually found in septic conditions. Chills frequently occur with the fever.

5. The *general health* usually suffers to some extent. In children if the foreign body is retained for some time there is a decided retardation of growth, both physical and mental in some instances. The former is the more common. Clubbing of the fingers and toes is common in chronic cases. Death results from septic infection or from some accident, such as profuse hæmorrhage, pneumothorax, or empyema.

It is to this group that the majority of the chronic cases belong. In some cases, such as pins, there may be decreased expansion only. If obstruction occurs the signs are those of involvement of a lobe, or rarely the whole lung, which shows decreased expansion, diminished or absent vocal fremitus, dullness or flatness, and variable signs on auscultation. The sputum is purulent, there is fever, and the X ray study shows lung tissue which gives a dense shadow. The two conditions for which these cases are mistaken most often seem to be tuberculosis and empyema. The mistake of regarding such a condition as pulmonary tuberculosis has very little excuse. If the process is in a lower lobe, as is common, this is in itself against tuberculosis, and despite marked signs and profuse sputum, tubercle bacilli are not found. If a whole lung is involved, with such extensive changes due to tuberculosis, the other lung should show disease. *Empyema* seems to be diagnosed much more often, judging by the number of our patients who give a history of having been aspirated. A smaller, but a surprisingly large relative number, have had the pleura opened on account of the incorrect diagnosis of empyema. A careful study of the physical signs should prevent the error. Vocal fremitus is rarely absent, although it may be greatly diminished. The resistance is not as marked as that given by fluid, and to this great importance should be given. The area of dullness may correspond to the lobe, and this is not characteristic of fluid. Shifting dullness is not obtained. Smaller areas of dullness may suggest encapsulated fluid. If there is difficulty the use of the needle and the X ray study should prevent error. In our cases with empyema as a complication there has been no difficulty in its recognition. The signs on auscultation may vary from day to day, and as many râles are often present they speak against fluid. If the heart is displaced it is likely to be towards the affected side, not away from it as in empyema. (Fig. 8 on Special Plate.)

From animal organic material, such as pieces of meat or bone, it is interesting to note that the reaction caused is not much greater than that due to metallic substances. Pus seems to form more rapidly, but the general course of events is much the same.

Neoplasm of a Bronchus.—This rare condition may simulate the signs of a foreign body very closely, especially if, as in a case under observation at present, the growth almost completely plugs the bronchus. In this patient the signs were in a lower lobe. There had been repeated severe hæmorrhages. New growth was suspected and its presence verified by bronchoscopy. The X ray plate taken after bismuth had been introduced into the bronchus showed the rounded outline of the tumour very closely.

Aneurysm and Enlarged Mediastinal Glands.—It is evident that if these cause pressure on a bronchus signs suggestive of foreign body may be found. No difficulty has arisen from aneurysm, but in some few cases of enlarged glands there has been doubt for a few days. This is especially likely to occur if there is a calcified gland situated so that in the X ray plate its position suggests that it may be an object within a bronchus. Careful study and observation for a short time usually give the diagnosis. An object in a bronchus of the size of the shadow would cause complete blocking which gives definite signs, much more marked than those due to the pressure of enlarged glands.

Foreign Body in the Œsophagus.—If this is obstructive, food and secretions enter the trachea and give general signs on auscultation. Considerable irritation may be set up and suggest a foreign body in the air passages. The absence of local signs, the X ray study, and direct examination give the diagnosis. In one patient ulceration in the œsophagus from a foreign body caused perforation into the air passages and gave a puzzling picture.

Exploratory Bronchoscopy.—If other methods have failed this should be done, needless to say by competent hands. The direct inspection of the bronchus to each lobe gives information, as Dr. Jackson says, as does cystoscopy of the appearance of the ureters. It may be said that we have had to use this method very rarely. It is very useful in cases of abscess or bronchiectasis in which there may be a question of the presence of an object, such as a tooth, which does not show clearly in an X ray plate.

The *position* of a foreign body can usually be determined with accuracy if it causes any degree of obstruction. The signs are in the area of lung supplied by the obstructed bronchus and, as a rule, are well indicated. If granulations have formed and extend upward so as to involve a higher bronchus the site of obstruction can be determined, but the foreign body is below this. In opaque objects the X ray study gives the answer. With a structure such as a pin it may be possible to determine the lung involved but not the bronchus, although marked limitation of movement below, rather than above, speaks for a lower lobe bronchus. The presence of signs on auscultation due to secretions rarely gives difficulty.

The *character* of the foreign body may be determined by the history. Some vegetable substance is suggested by marked general features, fever, toxæmia, &c. The curious fine râles sometimes heard over the area where a small metallic body is situated may be suggestive. Naturally, in the opaque group the X ray study is essential. Whether the blocking is complete or partial the situation gives some idea of the size. The diagnosis of the character of the foreign body is most important in the vegetable group as they are the most dangerous to life.

PROGNOSIS.

This is not to be stated in any set terms, as can be inferred from the great differences in the effects produced by various objects. When a foreign body has gained entrance to the trachea or bronchi there is naturally the hope that it may be expelled without interference. This does occur, but in a very small percentage; in Jackson's experience it has been in 2 per cent. of the cases. It may be soon after aspiration or a long time later, when with coughing the object may be expelled with a large amount of pus. We have seen, in rare instances, in cases in which several portions of a peanut had been aspirated, that after removal of one portion by bronchoscopy a smaller portion was coughed up subsequently. But in estimating the prognosis the slight chance of removal in this way should receive very little consideration.

Any object which has gained entrance to the air passages can be removed by skilled hands. In Dr. Jackson's clinic there has been a successful result as regards life in about 99 per cent. Almost all the deaths have occurred in the nut cases, despite removal. There is no instance of failure to remove the foreign body when sufficient opportunity was given. In one instance, mentioned previously, death occurred from hæmorrhage before the foreign body could be removed. It had been present for 36 years and new growth had developed. The great majority of the removals were done by Dr. Jackson; some were done by his assistants Dr. G. Tucker and Dr. L. F. Clerf.

The character of the foreign body is of the greatest importance. The substances of vegetable origin are in a special class. The evidence suggests that in practically every case, if the object is not removed, death follows. This may be in a few days, from the severe septic tracheo-bronchitis plus toxæmia, or result some time later from gradual exhaustion plus infection. A few patients may survive long enough for abscesses to form, but in these death, if delayed, is no less sure. Age plays an important part; the younger the child the more severe the symptoms and the greater probability of death occurring in a few days. The time between aspiration and removal is important, as the shorter stay of the foreign body the better the outlook. But even here early removal may not save the child, as in two cases quoted, one of a peanut and the other of a grain of corn, death resulted although the foreign body was removed on the day of aspiration. The degree of toxæmia is a useful guide. In general, it may be said that if the foreign body has been removed the outlook for recovery is better than the general condition suggests. Many children whose condition is desperate recover in a surprising way.

In the group of inorganic substances with skilled bronchoscopy and removal within a short time of aspiration the outlook is excellent and recovery is almost certain. As regards life the danger comes late from suppuration and abscesses. These cases differ in no way from such conditions due to other causes as long as the foreign body is not removed. If this is done then one can say that the outlook is always much better than in such cases due to other causes. The removal allows drainage and the improvement is often surprising. In this group the character of the foreign body plays a large part. One which causes little, if any, trauma and does not interfere with the entrance of air and drainage may be followed by slight change. An irregular mass, such as a tooth or an object with sharp edges, which injures the mucosa, is a much more serious matter. In the great majority of cases in which there has been abscess formation or bronchiectasis, the patient has recovered good health. There may be changes left in the lung but the restoration of function is remarkable.

With a foreign body in the trachea or one in a main bronchus which may be expelled into the trachea the outlook is always uncertain, as the foreign body may become impacted in the larynx following cough. After removal of the foreign body or bronchoscopy in young children there is always the danger of a marked increase in the usual subglottic swelling. This may come on or increase suddenly, and unless tracheotomy is done promptly death results. The care and skill which are available have an important bearing on the outcome in such cases.

TREATMENT.

Removal of the foreign body is indicated; the technical details it is not in my power to discuss. Certain aspects of the problem may be noted briefly. The patient with a movable foreign body in the trachea is always in danger of impaction in the glottis when the object is forced up from below by cough. Hence efforts to favour removal by inverting the patient are contra-indicated. In the patients with subglottic œdema there is always danger of complete obstruction. The question of tracheotomy should always be in mind, and this should not be delayed too long. Naturally, no set rules can be given for this, but it is better to do some tracheotomies which might not be necessary than to lose a patient by delaying it too long. Efforts to remove a foreign body by the fingers should not be made.

With a foreign body in a bronchus it is important to take time to study the patient thoroughly, unless perhaps in the very acute and severe cases due to vegetable substances. If the child is exhausted from a journey it is important to give opportunity for rest. There is no special treatment required in preparation for bronchoscopy. In patients with pneumothorax or empyema careful study of the whole problem is advisable before deciding as to the procedure. In our cases we have drained the empyema first.

After bronchoscopy in young children the danger of subglottic œdema must be kept in mind and the child watched constantly so that tracheotomy can be done when required and not delayed too long. If there is much secretion or an abscess is present it is an advantage to use the effect of gravity in aiding drainage after removal of the foreign body.

The physician may be asked to decide as to the wisdom of bronchoscopy in a child who is desperately ill with a foreign body in the air passages. Naturally, something must depend on the skill of the bronchoscopist who is available. In properly trained hands it seems wise to proceed with bronchoscopy as giving the best chance of recovery.

An Address

[ABRIDGED]

ON

MENTAL STATES IN ALCOHOLISM.

Given before the Society for the Study of Inebriety on April 8th, 1924,

BY BEDFORD PIERCE, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE RETREAT, YORK.

WHEN full allowance has been made for the large number of cases in which alcoholic indulgence is only a symptom of some underlying mental disorder, it remains true that alcoholism is the principal cause of a serious amount of insanity. We find that the forms of mental disorder associated with intemperance present an extraordinary variety of clinical states, covering almost the whole range of psychological medicine. Nevertheless, the clinical examination of a patient with alcoholic insanity rarely discloses symptoms which are in themselves a trustworthy guide to the cause of the disease. In other words, with one or two exceptions, the alcoholic psychoses present few specific features.

THE ALCOHOLIC PSYCHOSES.

Bevan Lewis, in his text-book, gives one of the best clinical descriptions of the alcoholic insanities. He divides them thus: 1. Acute alcoholic insanity. 2. Chronic alcoholism (*a*) amnesic form, with or without delusions; (*b*) chronic delusional form; (*c*) dementia. The attempt to subdivide accurately the clinical states confirms the conclusion that states produced by alcohol are apt to be indistinguishable from those produced by other agents. This, of course, raises the question whether these various mental states depend on the particular disturbing agent producing them, or on the individual's constitutional make-up and mode of reaction. In any case, we may safely conclude that the problem is not merely one of alcohol or no alcohol, but of temperament, personality, and nervous organisation.

We will now consider some of the clinical varieties of mental disorder due to alcoholic intemperance.

Alcoholic Delirium (Delirium Tremens).—This is more specific in its general features than any other mental disorder attributable to alcoholic indulgence. The combination of tremor with delirium is practically unseen elsewhere. By itself neither symptom is peculiar to alcoholic patients; but the syndrome known as delirium tremens can hardly be mistaken for anything else. The relation of the delirium to alcohol, however, is by no means clear. My experience confirms that of Dr. Hare and others, who look upon the delirium as essentially a deprivation symptom. The patient has acquired a toleration for alcohol; he has come to find that a considerable quantity is necessary to enable him to carry on his work, and if for any reason he cannot take or assimilate his accustomed quantity delirium appears. The rapid improvement that follows the administration of alcohol in early cases of delirium is strong evidence that this view of the matter is correct. But we have still to explain the delirium itself, and the suggestion has been made that it is due to a secondary toxæmia. Jauregg advanced the theory that excessive indulgence in alcohol produced an antitoxin which enabled tolerance to be established, and that delirium was caused by an excess of this antitoxin. It has also been claimed that the serum of confirmed alcoholics yields a toxin that will produce delirium in dogs.

Transient Mania (*Mania a potu*).—This condition occurs after, or in the course of, a drinking bout. It sometimes arises from a peculiar susceptibility to alcohol. One man, after a single glass of whisky, will become violently aggressive, while another may become homicidal without losing consciousness. But much more serious are the automatic unconscious states that sometimes occur, during which disasters happen which afterwards are not remembered. Almost any newspaper we pick up records a crime committed during intoxication.

Acute Alcoholic Hallucinosis.—This form of mental disorder attacks persons who have been drinking heavily for a long time. It differs from delirium tremens in that the hallucinations are more coherent, and fit in with delusions—probably of suspicion or persecution—which usually lead to acts of violence.

Polyneuritic Psychosis (*Korsakov's Syndrome*).—Long-standing alcoholic intemperance is the most common cause of this disorder, but it occurs also in chronic poisoning by arsenic, lead, and mercury, and in other diseases causing neuritis—e.g., diabetes and septic poisoning. The peculiar symptoms from our point of view are the extraordinary loss of memory for recent events and the extreme dissociation. Here the pathologist can suggest an explanation, as distinct degeneration of nervous elements can be observed. This affects either the peripheral nerve fibres, or the cortical fibres, or both, and it is assumed that the clinical symptoms vary according to the region first attacked. The peculiar tendency to fill up gaps in the memory by fictitious statements is not easy to explain. The senile patient who cannot remember is conscious of his defect, and is very clever in evading questions calculated to expose it. But in the disorder we are considering the patient does not know that he has a bad memory; and on being asked a question he replies promptly with any statement that the inquiry may have suggested. Not only the memory, but the self-critical faculty is absent.

Other Types of Mental Disease.—Many other types of mental disease arise from habitual intemperance; indeed, they are so numerous that it will be impossible to describe them. The most common is a mild state of mental enfeeblement, which may escape the notice of a casual observer, and cannot be called dementia. But it is quite apparent to intimate friends and those who can contrast the present with the past. In some cases there is a progressive amnesia, which may be due to a complication such as arterio-sclerosis. Another common type begins with delusions of suspicion, and rapidly reaches a paranoiac condition. Hallucinations of hearing are frequent; and the delusions generally refer to persecution by unseen enemies. Such patients are often homicidal, and are perhaps the most dangerous persons under care in mental hospitals. The duration of the illness is usually shorter than in true paranoia, and advancing dementia softens the clinical features. Between these prominent types are large numbers of cases, many of whom, when compelled to abstain, settle down in their guarded surroundings and become excellent workers. They do not recover, but they do not deteriorate further. I can only mention the epileptic type and the pseudo-paralytic type, which may present an exact picture of general paralysis in speech, gait, and behaviour. Again, there are cases of maniacal excitement, of depression, and of confusion, whose protean nature makes description impossible.

ALCOHOL AND INHIBITION.

Turning now to consider the immediate effects of a single dose of alcohol, it is generally agreed that it is not a stimulant but a sedative. Even when a dose is followed by increased ease in performing certain actions, this is due, not to the direct stimulus afforded, but to the removal of inhibitions. The usual formula is that alcohol tends to weaken and paralyse nervous functions, attacking the higher centres before the lower, and affecting qualities acquired late in the history of the race, such as self-criticism, before the more primitive qualities. I confess that I am perplexed when I try to set up a hierarchy of mental qualities, nor am I sure that the inhibitions weakened by alcohol are necessarily high. How many people, for example, have been too self-critical to create anything of moment! Be that as it may, however, there is no doubt that alcohol, even in moderate doses, is a sedative, and tends to weaken our mental powers. That the main reason for its consumption is the sense of well-being that it produces is more doubtful. Some good observers report that they are conscious of no such feeling, while in a few persons a dose of alcohol is followed by malaise or depression. It has been contended that the sense of well-being, or euphoria, is a secondary effect, depending on the company present and other extraneous conditions. Prof. Starling best expresses the view that alcohol is taken chiefly for the purpose of enabling an individual to forget the worries and perplexities of life. It certainly appears to induce a selective process in the memory, or perhaps, more correctly, the attention, whereby the painful facts of life are forgotten or unheeded. But yet its primary effect can hardly be on the memory, which is by no means one of the lately acquired mental attributes. In this connexion I remember very distinctly a mountaineering episode. We were on the return journey; I was physically exhausted, and I had lost all my courage. I simply dared not face the descent of a rude staircase cut in the ice until the guide pulled out his flask. One draught, and in five minutes I had accomplished the descent! But what had that to do with memory or even intelligence? I was perfectly aware of the risk I ran, but my fear of it had vanished; I did not doubt that I should keep my footing.

ALCOHOLISM AND INSTINCT.

Without entering on a discussion of Dr. Stoddart's view that "the alcoholic drinks enough to let his unconscious have its fling, and thus finds happiness," or examining the ground covered by the psychoanalytical school, it seems clear that many of the symptoms of temporary intoxication, as well as those occurring in alcoholism, may be regarded as arising from disturbance of the instincts. As the late Dr. Rivers said: "The altered behaviour which follows the taking of excessive amounts of alcohol can be traced to the over-action of instinctive and other early tendencies normally kept under control by the higher levels of mental activity." The connexion between the instincts and insanity in general, which was made clear more than ten years ago by Sir John Macpherson, has occupied many workers; and here, following their line of thought, we may briefly trace the relation of alcoholism to the three primitive instincts—the herd, the sexual, and the ego.

1. *The Herd Instinct.*—We find that small doses of alcohol tend to promote conviviality, and lead to a relaxation of social conventions. This is seen in

public-houses or on festive occasions. In a minority of cases, however, the tendency is to drink in solitude and to escape from all social claims.

2. *The Sexual Instinct* is markedly affected by alcohol. It becomes less under control, and crimes of passion, and indecencies of all kinds, are the result. Dr. Sullivan said that in half the convictions for sexual offences the influence of alcohol could be traced.

3. The *Ego Instinct* is conspicuously affected. I have spoken of the dispersal of fear by "Dutch courage." Self-criticism is in abeyance, and the alcoholic does not realise the effect of the drug upon him. Commonly there is greater self-satisfaction, and a sense of power, which degenerates into callous disregard of the claims of others. Altruism tends to disappear. Then there is the reaction of remorse, often leading to suicide. In pathological states there are delusions of suspicion which may end in homicide. Dr. Sullivan tells us that three-fifths of the total number of crimes of violence are due to alcohol, although in such crimes as theft and forgery its influence appears to be negligible.

It may be suggested that the primary influence of alcohol is on the vegetative nervous system. That it produces a dilatation of the peripheral vessels is well known, and possibly it also acts on the nervous mechanisms involved in the expression of the emotions, including the endocrine organs. But where so much is vague and uncertain it is difficult to draw conclusions. Until we know more of the physiology of the nervous system and its relation to instinct, we are unable to speak with confidence on the mental action of alcohol. Meanwhile we cannot but marvel at the extraordinary changes produced in human beings by the taking of a small quantity of this well-known chemical substance!

SCARLET FEVER OTITIS.

BY E. H. R. HARRIES, M.D. LOND.,
MEDICAL SUPERINTENDENT, BIRMINGHAM CITY HOSPITAL, LITTLE BROMWICH;

AND

F. BRAYSHAW GILHESPY, M.R.C.S. ENG.,
CONSULTING AURAL SURGEON TO THE HOSPITAL; HONORARY ASSISTANT SURGEON, BIRMINGHAM EAR AND THROAT HOSPITAL.

SCARLET fever, as judged by case-mortality, is, in its present phase at any rate, a comparatively mild disease. During the last 15 years case-mortality has declined from what was then considered the low figure of about 3 per cent. to the 1 per cent. of the present day. There has been a decline pari passu in the incidence of complications. These are, however, still sufficiently numerous and important to demand the utmost that can be done for their prevention, and failing that, for their treatment.

The nasopharynx being primarily and invariably involved in every case of scarlet fever, which is, as Trousseau observed, a "maladie essentiellement angineuse," it is only to be expected that complications arising from direct spread of infective material from the nasopharynx—e.g., otitis media—should play an important part in the clinical picture of the disease. Many estimations of the percentage incidence of scarlatinal otitis have been made. Writing in 1909 Hunter,[1] basing his figures on cases treated at the London Fever Hospital, gives an average of otitis in a total of 648 cases of scarlet fever treated during 1904–07 (four years) as 10·6 per cent. (mastoiditis 0·7 per cent.). Yearsley[2] quotes the Metropolitan Asylums Board figures for 1906 as 13·21 per cent. (of whom 0·68 per cent. had mastoid abscesses) of 17,829 scarlet fever admissions. In 1907 the percentage of otitis from the same sources was given as 11·4 per cent.

An analysis of cases admitted to the Birmingham City Hospital for the two years 1921–22 shows that of 3684 patients admitted with a diagnosis of scarlet fever "280 cases either had on admission or developed during their stay in hospital running ears on one or both sides. This number represents 7·6 per cent. of the crude scarlet fever admission figure. Of 122 cases of otitis during 1921, 22 had running ears on admission, and in nearly every one of these cases the discharge was of long standing. Scarlet fever could not therefore be blamed in these instances. On investigating the origin of the otorrhœa in these cases it was found that in the majority measles was the originating exanthem."[3]

Importance of Aural Complication of Exanthemata.

One of us (F. B. G.) recently examined 100 consecutive cases of ear discharge in elementary school children under 14 years of age. It was found that in 18 per cent. measles, and in 19 per cent. scarlet fever was stated by the parents to be the starting-point of the disability. Various figures have been adduced to show to what extent the exanthemata are causal of the chronic discharging ear of adult life.

Kerr Love[4] places the responsibility of measles at 23·7 per cent. and of scarlet fever at 15·8 per cent. Although there has been a reduction in the incidence of scarlatinal otitis during the last 15 years, it is clear that the aural complications of this disease still present a serious otological problem, and when account is taken of the similar destruction wrought by measles, which equals, or possibly exceeds in its extent that due to scarlet fever, it is obvious that the prevention, if possible, or at any rate the mitigation of these aural complications constitutes an important task for preventive medicine. In our experience an otitis media occurring in the course of an attack of diphtheria (as distinct from combined diphtheria and scarlet fever) and from which true *virulent* diphtheria bacilli can be recovered, is very rare. Mere morphological diagnosis of bacilli present in the discharge is useless, since diphtheroids are recoverable from many ear discharges. (A virulence test of the organisms is essential.)

Age-incidence of Scarlatinal Otitis.

It is of interest, and we think of importance, further to analyse the incidence of scarlatinal otitis occurring in age-periods. We have done this for the cases admitted to this hospital with a diagnosis of scarlet fever during two complete years 1921–22. It should be noted that Table I. represents the crude admission figures uncorrected for errors in diagnosis, and further does not differentiate between those cases which developed otitis during stay in hospital and those who already had it upon admission. It does, however, represent the extent of the otological problem at this hospital, and indicates the age-group which presents that problem most acutely.

TABLE I.

Age-period.	Cases of scarlet fever.	Cases of otitis.	Percentage in age-period.
0– 5	758	117	15·4
5–10	1686	132	7·8
10–15	703	24	3·4
15–20	192	7	3·6
20 plus	245	10	4·0
	3684	280	
	7·6 per cent.		

It will be seen that although the greatest number of admissions (45 per cent. of the total) are of children aged between 5 and 10, and that this age-group provides 40 per cent. of all cases of otorrhœa occurring in the scarlet fever wards, yet the percentage incidence in the various groups is very different. Of the children admitted at ages 0–5, 15·4 per cent. developed otitis—a percentage incidence twice as high as in the 5–10 group, and approximately four times as high as in either of the remaining age-groups. The percentage incidence for all ages was 7·6.

[1] Hunter, Wm.: The Practitioner, 1909, lxxxi., 1, No. 487.
[2] Yearsley: Ibid.
[3] Report, M.O.H., City of Birmingham, 1922, p. 57.
[4] Kerr Love: Diseases of the Ear in School Children, 1919.

Now, low as the case-mortality at all ages of notified cases of scarlet fever is at the present time, it will be seen from the following table (Table II.) collated from the Birmingham Health Reports for 1921–22 (the same years as are under consideration above), that the case-mortality per cent. from 0–5 is considerable.[5]

TABLE II.—*Percentage Mortality of All Cases of Scarlet Fever Notified in the City of Birmingham in 1921–22 According to Age-groups.*

Ages in years.	Cases notified.		Deaths registered.		Case-mortality percentage.	
	1921	1922	1921	1922	1921	1922
Under 1.. ..	23	28	2	1	9	4
Between—						
1– 2.. ..	91	83	10	6	11	7
2– 3.. ..	142	161	5	10	4	6
3– 4.. ..	175	161	2	1	1	1
4– 5.. ..	219	196	3	3	1	2
5–10.. ..	1599	1452	12	9	1	1
10–15.. ..	710	710	4	2	1	0
15–20.. ..	160	205	0	1	0	0
20 and over	210	263	2	3	1	1
—	3320	3250	40	36	1	1

The period 0–5, then, is responsible for the greatest case-mortality from the disease, and also for the greatest percentage incidence of otitis. These young children die not from toxic scarlet fever, but from the septic type, characterised by rhinitis, otitis, and adenitis, and terminated all too frequently by septic broncho-pneumonia. They have an overwhelming infection of the nasopharynx. An analysis of cases admitted during 1922 shows that the incidence of otitis and rhinitis (at all ages) was highest during the first quarter of the year, and lowest during the last quarter.

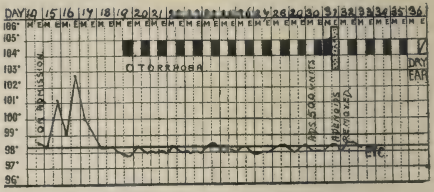
Operative Measures.

From the preceding remarks it will be seen that the running ear of scarlet fever is a frequent complication of the malady, and if untreated is the cause of a great deal of the chronic otorrhœa in school and adult life. Further, our figures would seem to point to the fact that this complication is more liable to occur under the age of 5, when the nasopharyngeal infection would find a suitable nidus in the adenoid mass generally present at this age. The Eustachian tube from its position and relatively larger size in infants would, at this age, be expected to carry the infection to the middle-ear readily. It would appear, therefore, that if infection from the nasopharynx could be eliminated early in the onset of a scarlatinal otitis, further infection through the Eustachian tube would be prevented, and the course of the complication considerably shortened. Yearsley, as long ago as 1909, suggested the advisability of removing the adenoid mass during the convalescence of scarlet fever as a means of aborting the ear discharge. Treatment of the nasopharynx by douching, as formerly practised, can only be mentioned to be condemned as productive of more untoward complications than good. Surgically it would appear that two indications are manifest in dealing with the infection of the middle-ear—i.e., (1) removal of the initial focus of infection—e.g., the adenoids (and tonsils, if also sharing in the infection), (2) release of the pent-up secretions of the middle-ear—i.e., paracentesis of the drum-head.

The theoretical merits of the above principles are beyond dispute, but on their practical application opinion appears to be divided. Layton in his report to the Metropolitan Asylums Board for the year 1920–21 says on the subject of paracentesis of the drum-head, "In my opinion it is upon the early and efficient performance of this operation in every case in which there is bulging of the drum-head that the success or failure of any organisation set up by the Board for the prevention of chronic otitis will depend," and he goes on to say that in the vast majority of cases if this operation is performed at the right time the inflammation of the ear will clear up and chronic ear discharge will not ensue; at the same time he draws attention to the necessity of using a general anæsthetic for this operation.

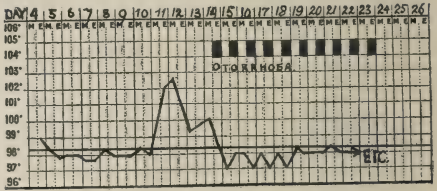
With the above statements we agree in great part, but the following considerations require attention. Scarlet fever and measles most often occur during the first ten years of life. In a hospital with special facilities of light for inspecting ears, and for operative purposes, the diagnosis of a bulging membrane in an infant of 3 or 4 years of age is a great deal easier than in a private house, where we consider that the practitioner in charge of the case is called upon to perform an intricate and delicate operation under conditions which are often extremely adverse. Further, others have doubted whether the results are so uniformly successful as above suggested, and we would here remark that no figures for such cases are recorded.

CHART 1.



Illustrating premonitory pyrexia. (Scarlet fever No. 602, 1923, aged 1 year 4 months.)

CHART 2.



Illustrating premonitory pyrexia and result of removal of adenoids. (Scarlet fever No. 1118, 1923, aged 8, desquamation on admission.)

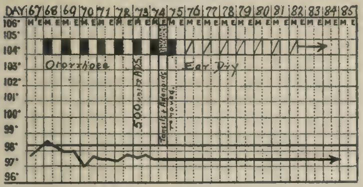
To come to what in many cases must be the primary focus of infection—the post-nasal catarrh and methods of dealing with this. It has been the practice of this hospital during the last year to devote a separate ward to cases of scarlet fever with otitis. All such cases are transferred to this ward and barrier-nursed. If the ear does not respond successfully to local treatment, and it is thought that the condition or amount of adenoid tissue is responsible for the continuation of the discharge through obstruction or infection of the Eustachian tubes, then operation to remove the adenoids (and the tonsils, if obviously infective) is performed. In the average case of scarlet fever without other complications this can be done with safety in the fourth week of disease. We have found that cases responded to removal of the adenoids alone, as satisfactorily as those in which the tonsils were also removed. If the adenoids alone are removed, we consider that this operation is productive of far less shock and risk of hæmorrhage than if the tonsils are removed at the same time. If at this stage the perforation of the membrane is considered inadequate for drainage it is enlarged from the existing perforation. A prophylactic dose of diphtheria antitoxin is given before operation. So far no complications have attended this line of treatment, which has been given a lengthy trial in Edinburgh by Gardiner.[6] The following figures from this hospital[7] may be of interest. Before an ear ward was established, or special supervision of ears undertaken, the average duration of the running ear in cases treated by routine methods was about 40 days from onset.

---

[5] Reports, M.O.H., City of Birmingham, 1921–22.

> "In 1921, 108, or 89 per cent. of the total of 122, cases of scarlet fever otitis were ultimately discharged with dry ears, including three upon whom a modified mastoid operation had been performed. Three died [from other complications] and 11 were discharged from hospital with ears still running. Superficially these results may appear to be fairly satisfactory, inasmuch as a large percentage of cases left hospital with dry ears, but they are not necessarily so because in most of these cases the source of the running ear had not been removed. There is little doubt that the ears in a number of these cases started discharging again after leaving hospital, resulting in chronic otitis, and possibly ultimate deafness."

CHART 3.



Illustrating symptomless late onset of otorrhœa and speedy success of operation. (Scarlet fever No. 423, 1923, aged 3, pigeon chest. Previous illness, measles.)

The average duration of the ear discharge in 20 cases treated in a special ear ward with efficient means of examination and treatment, but without operation, was 32·4 days. The last 50 cases treated by removal of adenoids, as well as paracentesis where necessary, were dry in an average of 15·8 days. Gardiner's Edinburgh figures show a great similarity.

Clinical Manifestations of Scarlet Fever Otitis.

The clinical manifestations of the onset of scarlet fever otitis are as follows:—

1. The onset in about half of the cases is painless; if occurring in the acute stage of the disease, pain is more liable to be complained of than when the complication arises during convalescence.
2. A small rise of temperature should always suggest an examination of the ears. The following charts show that this rise often precedes the otitis by a day or more. Timely paracentesis in these cases should be of value (see Charts 1 and 2).
3. Symptomless discharge may be the first indication. In our belief, in early life the membrane ruptures extremely easily, probably owing to its finer texture at this age. We have found that this mode of onset is more common in children under 5 (Chart 3).
4. In our experience mastoid complications are rare under 5 years of age. Two only out of a series of 16 consecutive cases of mastoiditis occurred in children under 5, a figure out of all proportion to the incidence of otitis in this age-group (Table I.).

We wish to record our very strong agreement with Gardiner that scarlet fever does not, as a rule, cause a rapid destruction of the membrane in the early stages of the disease if properly treated. In the last six months at this hospital less than half a dozen cases have been discharged with large perforations, and in the majority the perforation had completely healed before discharge. From the point of view of preventive medicine we hold that this fact is important, for an ear with a perforation is more prone to future attacks of suppuration than if the membrane were intact. It would appear that early and energetic treatment is the most economical means of dealing with this large class of case.

[7] Report to M.O.H., City of Birmingham, 1922.

ORGANIC ARSENIC COMPOUNDS IN PULMONARY TUBERCULOSIS.

BY JOHN GUY, M.D., F.R.F.P.S. GLASG., F.R.C.P. EDIN.,
DEPUTY MEDICAL OFFICER OF HEALTH, EDINBURGH;
AND
G. B. PAGE, M.D. EDIN., D.P.H.,
ASSISTANT TUBERCULOSIS OFFICER, ROXBURGH COUNTY COUNCIL.

ARSENIC, a very old remedy in tuberculosis, is one of the few medicinal substances used in this disease which has withstood the test of time. Usually given as Fowler's solution, it is of value at one time or another in most cases of chronic pulmonary tuberculosis, and its action in glandular infection is frequently most satisfactory. Arsenic seems to do best when given over rather long periods in small doses, occasional intervals being allowed and no attempt being made to increase the dose. Watch must be kept for intolerance, which commonly manifests itself in the gastro-intestinal tract; and it must not be forgotten that arsenic sometimes seems to predispose a patient to an attack of herpes zoster, and that its prolonged use is stated to have brought about malignant disease of the stomach.

The work recorded in the present paper was undertaken in order to discover whether the modern organic preparations of arsenic offer any advantages over the older compounds, particularly in pulmonary tuberculosis.

Precautions against Undesirable Sequelæ of Administration of these Drugs.

The exhibition of these drugs is not entirely free from risk, and, as they are used for the most part by those engaged in treating venereal disease, a brief résumé of these risks and of the means employed to minimise them may not be out of place. The reactions consequent upon the absorption of these drugs may be classified shortly as follows:—

Immediate Risks.—Symptoms appearing as soon as the injection is made, such as a bad taste in the mouth, pallor, sweating, flushing, nausea, violent retching and vomiting, prostration.

Mediate Risks.—Symptoms appearing from a few hours to two days after injection—e.g., malaise, headache, nausea, vomiting, and pyrexia. These constituted the "reactions" so often seen with the older types of arsenobenzol.

Remote Risks (jaundice and general dermatitis).—A discussion as to the causes and the treatment of these accidents will be found in any up-to-date textbook on venereal disease. The more alarming immediate reactions are best met by the absolutely recumbent position, adrenalin subcutaneously, and, later, sips of black coffee. Repetition of immediate reactions is said to be prevented by the prior use of atropine hypodermically, but this is not quite true, and in a disease like pulmonary tuberculosis, where retching may bring on hæmoptysis, it is wiser to give up the treatment.

All these undesirable sequelæ may be minimised by the proper preparation of the patient, which is a simple matter. On the evening before injection the patient receives a laxative pill, and next morning a small dose of white mixture to ensure an action of the bowel without severe purgation. The patient remains in bed and is allowed for breakfast a cup of tea, one boiled egg, and two thin slices of bread and butter. We usually make the injections about 11.30 A.M. and an hour before a drink of glucose lemonade containing 6 dr. of glucose is given. At 1 P.M. a cup of clear soup is given, and if the temperature is normal and the patient well at 3.45 he is allowed up, provided, of course, that he is not confined to bed on other grounds. Our patients return to bed at the usual hospital hour (8 P.M.) and continue next day on the grade of rest or work which they happen to have reached.

Hitherto we have only had a couple of cases of immediate reaction—both after intramuscular injections—and we have not been troubled by the other risks mentioned. In choosing preparations for experiment we have made use of a well-known brand of the "914" type of arsenobenzol for intravenous injection, and of "sulfarsenol" for intramuscular medication. At the outset it was supposed that the intramuscular method would give the better results owing to its slower and more prolonged action. This has proved to be the case, so that only one or two patients have had full courses of intravenous arsenic. The sulfarsenol was dissolved before use in a solution consisting of pure anhydrous glucose 5 per cent., and guaiacol 0·5 per cent. in distilled water, and injected into actual muscle tissue in the upper and outer part of the buttock.

The intravenous arsenic was given in weekly doses of 0·3 or 0·45 g. up to six injections, the course being repeated after an interval of a month in some cases. Sulfarsenol was given intramuscularly in three different dosages, the second proving the most useful—viz., a purely tonic course of six to eight injections weekly from 0·12 to 0·24 g., a similar series of 0·30 g. after a smaller trial dose, and a course of bi-weekly injections such as might be used in treating syphilis. It is, perhaps, unnecessary to add that the urine must be tested for albumin before treatment is begun, and again for albumin and bile before each injection.

Pain after intramuscular injections is negligible so long as the injection is into actual muscle and the part is well massaged afterwards; no patient has refused or objected to the treatment.

Results of Treatment.

In estimating the value of this or any other forms of treatment in pulmonary tuberculosis, we are fully conscious of the difficulties met in a disease where the unexpected so often happens; where patients appear to get well without special measures, or having improved for a time, fall back without any discoverable cause. The cases selected have been few, but, with the exception of one, were sputum-positive; and so far as possible they have represented various stages and grades of the disease. All were afebrile, or nearly so, at the beginning of treatment. Only a dozen cases have been treated so far, three of whom were benefited sufficiently to warrant a second course. All showed various degrees of improvement except two, and these have both exhibited physical signs of extending disease. One has gone home as unlikely to benefit by further sanatorium treatment; the other has remained a patient with a reasonable hope of ultimate arrest. Both cases showed an increasingly positive complement-fixation test, and if this is to be interpreted as an increase of antibodies in the blood (increased resistance) the effect of treatment may have been more favourable than we supposed, since a negative C.F.T. occurring in a *pronounced* case of pulmonary tuberculosis usually suggests that resistance has, for a time at least, broken down.

The principal effects noted are those which one would expect from arsenic, but they have been obtained more rapidly and in a more marked degree than in control cases treated with liquor arsenicalis added to emulsion of cod-liver oil or with Blaud's pill with arsenious acid. After each dose there is an increasing tonic effect, a feeling of well-being, sharper appetite, and returning strength. The improvement in the appearance, colour, and weight of the patient is very marked. Anæmia disappears more rapidly than under routine sanatorium treatment. Diminution of sputum and decrease in the number of tubercle bacilli present therein, however, are only in accordance with the improved general condition. That is to say, these organic preparations of arsenic have no direct lethal action upon tubercle bacilli in any way comparable to their action upon spirochætes. In one case of double infection where intravenous treatment was carried on despite several attacks of hæmoptysis, it was noted that these accidents were not followed by any pyrexia or physical signs of spread. It is possible, therefore, that the injections may have exercised some retarding influence. The fact that the patient knows that something definite is being done for him must not be lost sight of, and the "ritual" demanded by the treatment is probably beneficial in itself—at any rate it acts as a wholesome brake on the tendency found in most sanatoria on the part of both attendants and patients to hurry too much over the rest period.

Another point of interest is that the majority of patients have shown an increasingly positive C.F.T. The significance of this is uncertain; does it mean increasing resistance? We do not suggest that the injection of organic arsenic should be used as a routine in the treatment of pulmonary tuberculosis, or that it is suitable for general use outside institutions. What may be claimed is that it is an excellent method of exhibiting the drug where it seems indicated, particularly where there is pronounced anæmia, or where vaccines are to be questioned on account of extent with activity, or again in the type of case often met with which makes some headway in a sanatorium and then "hangs fire."

Also, one may add, there need be no hesitation in treating actively cases of double infection with benefit to both conditions. In the case of young adults with limited lesions, who would do quite well no doubt under ordinary sanatorium treatment, we have been struck with the more rapid progress made when organic arsenic is given. If the period of hospital treatment can be shortened safely, something is gained both for the working-class patient and the ratepayers.

The following cases illustrate various points:—

CASE 1.—W. A., aged 29, admitted Feb. 19th, 1923, sputum + + +, C.F.T. + + −, W.R. − − −, well-marked disease both upper lobes and right lower lobe where it was progressing. Obtained limited benefit from sanatorium treatment and then came to a standstill with the disease spreading slowly. Intramuscular sulfarsenol begun June 22nd (six small weekly injections, total 0·97 g.). Treatment stopped on account of immediate reactions. Disease has ceased to spread. Sputum much diminished and bacilli found with difficulty. C.F.T. + + +. Patient is still in the sanatorium and is carrying out the highest grade of manual labour easily.

CASE 2.—F. A., aged 20, admitted June 4th, 1923, sputum +, C.F.T. − − −, W.R. − − −. Limited involvement of right apex, with considerable loss of weight and anæmia. Systemic factor readily controlled by rest. Sulfarsenol intramuscularly was begun on the 22nd (eight injections at weekly intervals, total 1·51 g.). As improvement was considerable, a further course (total 2·30 g.) was given a month after the first. Patient has lost his anæmia entirely and gained 19 lb. C.F.T. − − −. There is still a little sputum which has been repeatedly negative. Physical signs of disease are detected with difficulty and the condition appears to be arrested. Patient is doing the highest grade of manual labour with ease. L. D., aged 19, was a similar, but more extensive case, both lobes of the right lung and probably the left apex being affected. C.F.T. − − −, sputum +. He was given eight injections of sulfarsenol (2·34 g.), treatment being begun before he was quite afebrile. He has gained 26 lb. and is able to do an intermediate grade of outdoor work without disturbance. The sputum remains + and the C.F.T. is + − −.

The next illustrates the value of organic arsenic in diagnosis.

CASE 3.—The patient, a male aged 27, was admitted with a history of hæmoptysis a few weeks before and also while on service in France. Both hæmoptyses had been between 8 and 10 oz. There was impairment at the left apex with rather harsh breath sounds and chronic laryngitis. Sputum negative, C.F.T. − − −, W.R. + + + (repeated). A skiagram did not afford any assistance. There was no history of specified disease, and no other signs or symptoms to help one in arriving at a definite diagnosis. Before being placed on arsenical treatment, he had had a short trial under general sanatorium routine with no particular result. He was given a full course of sulfarsenol intramuscularly (3·54 g. arranged in 12 injections) and biniodide of mercury by the mouth. The symptoms cleared up entirely and his general health improved markedly. The W.R., as might be expected, remained + + + and he was transferred to another department for further treatment as an out-patient.

The following case is included to show the value of organic arsenic in a case of extensive lung disease with activity.

CASE 4.—L. J., aged 28, admitted May 12th, 1923. Sputum + + +, C.F.T. − − −, W.R. − − −. The patient had glands removed from the neck in 1916 and again later. He first came under observation for lung disease in 1922. On admission he showed extensive old-standing disease of the left lung with chronic dry pleurisy and more recent active disease at the right apex. Although he was an excellent and obedient patient, two months sanatorium treatment failed to accomplish any real improvement—both temperature, weight, and general condition remaining variable despite absolute rest. Sulfarsenol was begun July 19th (eight weekly intramuscular injections, total 2·34 g.). At the end of this course he had gained 15 lb., the temperature was nearly level, sputum +, and C.F.T. + + −. The right apex was still active, but the left lung showed evidence of healing and the pleurisy had disappeared. After a month's rest, a further course has been given (six injections, total 1·65 g.). The total gain in weight is 18 lb. and the patient states he has not been so well for over a year. The sputum is tending to decrease and bacilli are less numerous. This patient is by no means "out of the wood," but we feel that arsenic has helped him very definitely. This, too, is just the type of case in which vaccines might do incalculable harm. The alteration in the C.F.T., which has been checked several times, is interesting. At the moment of writing the patient is suffering from a little renewed activity in the right side and the C.F.T. has fallen to ± − −.

Conclusions.

The administration of the organic compounds of arsenic is a valuable measure in cases of pulmonary tuberculosis where arsenic seems indicated. The intramuscular route is preferred.

The types of case suggested for this treatment are:—

(1) Cases of extensive disease with some activity, where one would hesitate to use vaccines, but where there remains some prospect of producing arrest or extreme chronicity.

(2) Cases which "hang fire" after a period of sanatorium treatment.

(3) Cases in young adults with anæmia and loss of weight, but otherwise favourable. It is thought that the period of institutional treatment may be shortened.

(4) Cases of double infection — syphilis and tuberculosis.

(5) As a therapeutic test in doubtful cases of lung disease. With simple precautions there is no risk; the mischief which may follow tuberculins cannot occur.

The improvement obtained is due to a general stimulation of the metabolic functions of the patient; there is no specific effect upon the bacilli. Organic arsenic does not pretend to be another new cure for tuberculosis.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

The Prevention and Treatment of Congenital Syphilis.

A MEETING of this section was held in the Royal College of Physicians, Dublin, on March 14th, Dr. N. M. FALKINER, the President, being in the chair.

Dr. T. P. C. KIRKPATRICK opened a discussion on the prevention and treatment of congenital syphilis, dealing with the results he had obtained at the Lock Hospital and Dr. Steevens' Hospital, Dublin. He pointed out the difficulty there was in arriving at an accurate estimate of the incidence of congenital syphilis, but adduced figures taken from the returns of the Registrar-General for Ireland to show that the number of deaths from syphilis of children under a year old was the main determining factor in the total number of deaths recorded from that disease in Ireland. In addition to the loss of infant life, congenital syphilis was the cause of many disabilities in young adults. Dr. Kirkpatrick pointed out the importance of the Wassermann reaction as an aid to diagnosis in young people who do not present obvious stigmata of the disease. 114 syphilitic women who had come under observation had become pregnant of 148 pregnancies. Of these pregnancies 107, or 72·2 per cent., had resulted in healthy children, 22 in syphilitic children born alive, and 19 in dead syphilitic children or mishaps. In none of the failures had the women attended for sufficient treatment. The treatment advocated was the intravenous administration of some of the 914 preparations of arsenic, and the one generally used was N.A.B. Repeated doses were given during pregnancy and the administration controlled by Wassermann reaction of the blood. The results of the treatment of 63 congenitally syphilitic children was also considered. Dr. Kirkpatrick recommended the use of N.A.B. even in young infants, and detailed the history of several patients treated. His remarks were illustrated by lantern slides of charts of the women and children treated.

Dr. GIBBON FITZGIBBON said that before a department for the treatment of venereal diseases had been started in Dublin, he had treated many cases of syphilis with intravenous injections of N.A.B., and he had found that nearly always if he treated during pregnancy a woman affected with syphilis and whose W.R. was positive the child was born alive, and generally without any evidence of the disease. From time to time patients turned up at the Rotunda with a history of repeated death of the fœtus, who, when examined, showed absolutely no cause for the death of the fœtus, but when a Wassermann test was done it proved fully positive. After this, during the next pregnancy, these patients were treated with N.A.B. injections, and had living and perfectly normal children. The children were normal at any rate at birth, but of course it was very hard to follow up their subsequent history. Recently a woman had come back to the hospital who had been treated with N.A.B. injections during the previous pregnancy two years before, and the child had been born living and healthy, and had remained healthy since. Dr. Kirkpatrick's descriptions of the cases of syphilis which he treated conformed with his experience of cases which he had treated at the Rotunda Hospital.

Dr. L. L. CASSIDY said it would be interesting to know why so many cases aborted before the fourth month of pregnancy, and yet most careful examination of the patients showed no signs of syphilis whatever. In his experience not more than 3 per cent. of those mothers gave a positive Wassermann reaction. The main mortality during pregnancy in syphilitic patients seemed to occur after the fourth month, and very often in cases in which there had been no primary symptoms whatsoever. One sometimes came across patients with syphilis which only developed at the age of about 45 or 50, when the menopause took place. He thought that this type of syphilis was a very important one, and one which should be recognised in gynæcology. He would be glad to know if, in Dr. Kirkpatrick's opinion, in cases of death of the fœtus before the fourth month of pregnancy the carrier of infection could be the spermatozoa.

Dr. V. M. SYNGE was interested to hear that Dr. Kirkpatrick did not consider congenital syphilis was very infectious. He, personally, thought that it was. Dr. Kirkpatrick had also said that a child with congenital syphilis had its general resistance lowered, and was very likely to get infected with tubercle bacilli and other bacteria. He himself had seen a large number of cases of congenital syphilis, and he had never seen one which had developed tuberculosis. He asked whether cases which did not show any obvious clinical signs of syphilis, which were apparently quite healthy and yet in which the blood Wassermann was positive and the cerebro-spinal fluid negative, should be considered as being affected with syphilis, and if such cases should be vigorously treated in the same way as cases which had definite symptoms of congenital syphilis. He also asked how much N.A.B. should be given to children with congenital syphilis and how long the injections should be continued. Should mercury be given as well, or was N.A.B. alone sufficient for every case? If after treatment for some time the patient's W.R. remained negative, was it justifiable to say that that patient was cured? He, personally, did not think it was. He thought the only real test was if the child in after life developed syphilis. Could a woman with active signs of syphilis give birth to a healthy child?

Dr. **Pugin Meldon** said that when a woman came to him just after pregnancy for treatment he continued treatment with arsenical preparations, and he made every woman nurse her child, as he found that, although the arsenic was not excreted in the milk, some substance was excreted which had a beneficial effect on the child.

Dr. J. W. **Bigger** said that as a pathologist the point that interested him most was the results of blood-tests which were performed on cases of congenital syphilis. The figures mentioned by Dr. Kirkpatrick were extremely convincing of the good results of the treatment of syphilis. He, personally, was of opinion that the W.R. in cases of congenital syphilis was just as reliable as in the cases of ordinary syphilis, and he did not think that there was really much difference between congenital and acquired syphilis. The tendency in congenital syphilis might be to get longer latent periods than in acquired syphilis, and during the latent period in either disease one might get a negative W.R., but this certainly did not mean that the patient was cured, and in cases of congenital syphilis it was necessary to keep a watch on the patient longer than was necessary in cases of acquired syphilis In cases where the W.R. was considerably positive (and where one felt sure that no error had been made), and especially if there was a consistently positive sigma reaction, the case should be regarded with the greatest suspicion, and should be given the benefit of treatment by one of the arsenical derivatives.

Dr. W. C. **MacFetridge** said that lesions of congenital syphilis were often found at an advanced age, though many people held that they were not found after the age of 20. In connexion with ocular lesions one found them frequently in patients up to 60 years of age. Dr. Kirkpatrick, in his paper, attached great importance to treatment by arsenical preparations. At the Eye and Ear Hospital, although a great many of these cases were seen, patients with iritis, &c., very few of the surgeons at the hospital used arsenical preparations when treating these cases. He, personally, had never used them. This, however, was a point about which there was a great diversity of opinion. Some people in the treatment of ocular lesions said that arsenical preparations were of great value, while others said that they were of no use at all. He wondered if it was safe to treat cases of optic neuritis and optic atrophy with arsenical preparations; some ophthalmic surgeons said that in such cases arsenic should certainly not be used. He, personally, thought it would be safe to use them if the man who was giving them was very experienced in their use. Mercury was of great aid in the treatment of optic cases.

Mr. R. R. **Leeper** said that the question of the latency of syphilitic infection was an interesting one. One sometimes found patients who had had syphilis and remained pretty well after treatment, although not cured. These patients sometimes had healthy families, with no sign of mental disease, but yet years after the patient developed G.P.I. He wondered where the spirochæte was in the body during all these years. In G.P.I. patients spirochætes would be found all through the brain, but not in the spinal fluid.

Dr. R. H. **Micks** said that it was in the treatment of very young infants that most difficulty was experienced, as it was so hard to find a vein to inject the arsenic into. He had found milk injections very helpful, also mercury.

Dr. **Kirkpatrick** said, in reply, he agreed with Dr. FitzGibbon that it was very difficult to trace the source of infection in women who had syphilis and who produced syphilitic children. He thought that probably the syphilitic lesions were suppressed, especially in women who were pregnant. It was noticed that women who had syphilis often improved very much in their syphilitic conditions when they were pregnant. The question of how the infection was carried to the fœtus was a very difficult one. If a woman became affected with syphilis only at the times of pregnancy, the course of disease was greatly modified, and sometimes stopped altogether. It would be impossible to lay down definite rules about the length of time for which N.A.B. injections should be given. As long as the patient's W.R. was positive, and as long as the injections had no bad effects, he would give at least three courses of injections and perhaps more. If after this the W.R. was still positive, it generally meant that treatment would not do any good in that particular case. It was also impossible to lay down definite rules as to whether the giving of N.A.B. did harm to patients with optic atrophy and optic neuritis or not. In some cases perhaps it did, but he had seen some cases in which it had done a great deal of good.

SOCIETY FOR THE STUDY OF INEBRIETY.

At a meeting of this Society on April 8th, with Mr. C. J. Bond, F.R.C.S., in the chair, Dr. **Bedford Pierce** delivered an address on Mental States in Alcoholism, an abstract of which we publish on p. 841.

In the discussion which followed the paper, Sir **Robert Armstrong-Jones** said that while questions of ætiology were very difficult in general diseases such as arterio-sclerosis and nephritis, they were even more difficult in mental disease. He considered that alcohol was an important cause of insanity, that chronic delusions of a sexual nature were always due to alcoholism, and that paramnesia was invariably of alcoholic origin. Alcohol was first a stimulant and then tended to remove the inhibitions and restraints imposed by education. He objected to the limitation of instincts to the three mentioned by the lecturer—herd, ego, and sex—and was disposed to think there were as many instincts as primitive desires. Sir Robert Armstrong-Jones quoted the Commissioners of the Board of Control, who called alcohol "brain poison," and said that in his experience at Claybury, 20 per cent. of the male and 10 per cent. of the female admissions were clearly attributable to alcoholic indulgence.

Dr. **Percy Smith** referred to the fact that alcoholism was responsible for a large proportion of the most dangerous patients under care. He spoke of the crimes committed in automatic unconscious states, and of the difficulty of persuading legal authorities that such things could occur. He also spoke of the failure of the Inebriate Acts to control persons addicted to drink, and of the dangerous practice of giving alcohol to children, at the risk of their addiction to it in later life.

Dr. W. **Asten** mentioned the irritable disposition met with in many inebriates, and the difficulty of discussing treatment with them without giving offence. He asked whether this touchiness preceded or followed the alcohol addiction.

Dr. W. M. **Feldman** remarked that among Jews alcoholism was rare, while mental disorder was relatively common. On the other hand, there was reason to believe that mental deficiency, prostitution, and alcoholism were all recessive Mendelian qualities; and this suggested some connexion between them.

Dr. T. N. **Kelynack** alluded to the influence of suggestion in producing results. In many experiences where alcohol was commonly considered to be of service it seemed probable that the mere drug action of alcohol played but a minor part. Generally speaking, he believed that many of the medico-sociological advantages claimed for the use of alcohol, both in health and disease, were really due to the psychological action of so-called suggestion.

Reviews and Notices of Books.

THE LAW RELATING TO LUNACY.

By Sir HENRY STUDDY THEOBALD, K.C., M.A., Hon. Fellow of Wadham College, Oxford; lately a Master in Lunacy. London: Stevens and Sons. 1924. Pp. 890. £2 10*s*.

WELL-ESTABLISHED legal text-books renovated in successive editions cover so much of the ground over which lawyers have to travel in the practice of their profession that it must demand no little courage on the part of the author to become, as it were, the founder of a new one. The courage of Sir H. S. Theobald, handicapped by blindness, needs no comment, but rather the recollection that his qualification for his task is derived from 15 years' experience as a Master in Lunacy, following upon many years of practice at the Bar. His example will long be remembered. The work he has compiled, shorter by about 150 pages than the monumental "Archbold," contains all that is essential for the lawyer's guidance in studying any but the most abstruse points in connexion with lunacy law and practice, and he has found space for the introduction of interesting references to the history of his subject. Medical practitioners, however large their liabilities may appear to bulk at the present date, are chiefly concerned with lunatics as patients, after certification has taken place, and they will find all that they need know as to the legal position of lunatics clearly set out and explained in chapters on the care and treatment of the insane, including one entitled Miscellaneous Provisions. If they care to glance at the non-essential pages of the book they may be interested to trace the origin briefly outlined of the Royal prerogative now exercised by the Lord Chancellor, and having its probable source in rights over the property of the mentally defective summarily taken from the feudal lords by Edward I., or they can study the evolution of legal patronage in a chapter on the Masters in Lunacy, the office held from 1907 to 1922 by the author. It is not more than 65 years ago that Master Winslow was said to have "had peculiar views as to the proper destination of committees' balances in which the Lord Chancellor did not concur. Master Winslow resigned." His successor, too, was unfortunate. Sidney Herbert wrote to Mr. Gladstone, "Poor Thesiger has got into a dreadful mess in appointing his son-in-law (little Higgins) a Master in Lunacy." Master Higgins, who held office for two months only, was a clerk in the Colonial Office, whose legal qualifications were confined to his having married the Lord Chancellor's daughter! However, Sir Henry Theobald is charitable in his observations on the exercise of patronage which "savoured of excessive zeal in the service of relatives or friends," and observes that outside critics rarely know all the conditions of what may seem at first sight to be a political job. "Even Lord Chancellors," he suggests, "deserve the benefit of the doubt." One of the best known names among those of former masters, to students of Victorian literature, was, of course, Samuel Warren, author of "Ten Thousand a Year" and "The Diary of a Late Physician." "It has been said," writes Sir Henry Theobald, "that he drew a good deal of the latter book from the contents of affidavits in lunacy. Unfortunately for the story the book was published before he became a master."

DER AMYOSTATISCHE SYMPTOMENKOMPLEX.

By Dr. A. BOSTROEM, Privatdozent for Psychiatry and Neurology in the University of Leipzig. Berlin: Julius Springer. 1923. Pp. 205. 7*s*. 6*d*.

A RECENT edition to the excellent series of monographs in neurology and psychiatry edited by Profs. O. Foerster and K. Wilmanns is devoted to a consideration of the syndrome called by Strümpell "amyostatic," a term indicating sufficiently a "muscular astasia"—i.e., involuntary movements—with the corollary, variation in muscular tonicity. Dr. Bostroem, accordingly, is concerned with athetosis, chorea, and what he designates the "Parkinson-Westphal-Strümpell-Wilsonsche Krankheitsgruppe" in a somewhat omnibus fashion. Characterised by much erudition and a due appreciation of the contributions of others, this monograph is suggestive and thought-provoking in its main outlines, though its division of the amyostatic complex into the three groups of chorea, athetosis, and the above-mentioned disease class is obviously open to criticism. Further, some of the author's statements in reference to what he calls, briefly, "Parkinson-Wilson" are misleading if not erroneous—e.g., he holds that "involuntary spontaneous movements" are wanting in that group—a curious reading of the facts. The view that associated movements do not occur in the same class of case is also misleading if, as appears, the implication is that they are present or increased in the others, and that this may be used as a means of differentiation.

LE CERVEAU ET LA PENSÉE.

By HENRI PIERON, Professor at the Institute of Psychology of the University of Paris. Paris: Felix Alcan. 1923. Pp. 326. Fr.10.

THE age-old problem of the interrelation of brain and mind is approached afresh by Prof. Pieron in succinct and readable fashion. Undeterred by the trend apparent in certain quarters towards a complete cleavage between mind and its organ, he pleads for a closer approximation of physiology and psychology, pointing out with truth how frequently the exponent of the latter science is unfamiliar with the data of neuro-physiology and the rich material of the neurologist. He would have a dynamic psychology taking its place in the comity of the sciences, collecting and examining objectively the finest and most delicate reactions of cerebral activity. Chains of neurones form without question the "functional circuits" of thought, and within them exist systematised "groups" suggesting the reality of "centres" of a psychological order. The application of physiological method can illuminate not a few processes commonly called "mental"; this is particularly the case with the phenomena of speech. Prof. Pieron reaches no special conclusion, and studiously avoids any type of special pleading; but no reader of unbiased mind will fail to appreciate the force of his contention, that the activities of the human mind should be investigated from the physiological side no less than from the psychological.

THE UNSTABLE CHILD.

An Interpretation of Psychopathy as a Source of Unbalanced Behaviour in Abnormal and Troublesome Children. By FLORENCE MATEER, A.M., Ph.D., Psycho-clinician in the Ohio Bureau of Juvenile Research. London and New York: D. Appleton and Co. 1924. Pp. 471. 10*s*. 6*d*.

DR. Mateer has passed beyond the optimistic assurance that a diagnostic classification or a mental age test, of which the Simon-Binet stands as a type, is more than a reliable means of systematising observation. The problem of the psychopathic child is different from that of the feeble-minded, for educational or social crises occur in individuals whose mental age may be equal to or above the physical age. This book is an account of the work done and difficulties met in the Bureau to which the author is attached, and it rouses an uncomfortable feeling that in this country such work is almost non-existent. The author holds out the promise that, however great may be the needs and difficulties, the psychopathic child has potentialities and will repay care as no feeble-minded can. But this care involves more than correctional treatment carried out without understanding of the condition. Of such treatment she writes: "We check his reactions, add another load of fear, worry, shame, resentment, more inferiority, and new grievances against all in authority. . . . It is only the elasticity and resiliency of the child mind which keeps any of them from a re-enforced and more extreme type of behaviour."

The subject is handled on broad lines. It indicates the scope of the book when Dr. Mateer presents evidence that congenital syphilitics show a recognisable type of psychopathy peculiar to themselves, while she takes full advantage of whatever modern psychological methods have to offer in the study of individual cases. There is a pleasing modesty throughout the writing; the author makes no attempt to disguise the many perplexities, and yet offers plenty of useful material and observation.

St. Elizabeth's Hospital.

Clinics and Collected Papers of St. Elizabeth's Hospital, Richmond, Virginia. Vol. I., contributed by the Staff. London: Henry Kimpton. 1923. Pp. 560. 37*s.* 6*d.*

This book contains 66 papers written by the staff of a small hospital which only includes six medical members. It therefore represents a large output from individuals. A feature is the collection of articles on the management of the hospital. A great deal of thought has obviously been given to this side of the subject, an example which might well be followed by many nursing homes in this country. Only a few of the scientific papers have appeared elsewhere. They cover a very wide range of subjects, and a breadth of view runs through them which is undoubtedly related to the fact that extreme specialisation, such as has occurred in some hospitals, does not exist at St. Elizabeth's. The book is well illustrated and repays perusal.

Junior Regional Geographies.

Book III. The Regions of the World. By W. H. Barker, B.Sc., F.R.G.S.; and Leonard Brooks, M.A., F.R.G.S. London: University of London Press. 1924. Pp. 272. 2*s.* 9*d.*

This is the third of a useful series which, when completed, will form a general regional study of the world as a whole. All practised teachers agree that before attempting to impart detailed knowledge of continents and regions, their pupils should obtain some general notion of the world in which these continents are set. This volume gives a very good idea of the world as a living unit, and will be of use not only to the young pupil but also to the adult whose grasp of the relations and interrelations of the world is not as fresh as it was; indeed, quite advanced workers along special lines will find here useful information when they come to think of their subjects internationally—and this is the spirit in which many pathological problems must now be approached. Chapters on the industrial regions of Europe and of North America are especially valuable. Nearly one hundred well-chosen illustrations enhance the text.

Internal Derangements of the Knee-Joint.

By A. G. Timbrell Fisher, M.C., F.R.C.S. Eng., Surgeon (with Charge of Out-patients), Seamen's (Dreadnought) Hospital, Greenwich; Assistant, Surgical Unit, University College Hospital, London. London: H. K. Lewis and Co., Ltd. 1924. With 80 illustrations. Pp. xii. + 144. 12*s.* 6*d.*

In this monograph the author has presented his subject after a critical re-investigation of the fundamental, anatomical, and pathological principles which underlie the lesions grouped under the heading of internal derangements of the knee. The first part deals with the pathology and surgery of the semilunar cartilages and constitutes a safe and sound essay in itself. In the second part other varieties of internal derangement are considered, and in this section is incorporated much of the valuable original work recently carried out by the author in connexion with the pathology of loose bodies, and the pathogenesis of osteoarthritis.

The monograph deserves high commendation. To the author's own exceptional knowledge of the anatomy and pathology of the whole subject is added—in the form of foot-notes scattered throughout the book—a wealth of clinical experience derived from Sir Robert Jones. Sir Arthur Keith writes a foreword.

JOURNALS.

Journal of Physiology. Edited by J. N. Langley, Sc.D., LL.D., F.R.S. Vol. LVIII., Nos. 4 and 5. Cambridge University Press. March, 1924. Pp. 259–372. 10*s.*—Chelonian Respiration (Tortoise), by Thomas Lumsden. The author finds that the respiratory centres in this animal are the gasping centre at the apex of the calamus scriptorius, the expiratory centre just above this, and the apneustic centre above the level of the fourth ventricle. There is no evidence of the existence of a pneumotaxic centre, and the vagi do not appear to have any tonic-regulating effect on the respiration. Moreover, the respiratory needs of the tortoise are so slight that under ordinary conditions a single inspiration may last for two to three hours. The respiratory rhythm is more powerfully affected by variations in the temperature of the cells composing the respiratory centres than by variations in the activity of the general metabolic processes or in the gases respired. When, however, the temperature is constant, the amount of CO_2 in the blood appears to be the chief factor in the regulation of normal respiration.—G. V. Anrep and H. N. Kahn deal with the metabolism of the process of reconstruction of the submaxillary gland in the dog. They find that the recovery of an exhausted gland under normal conditions is a slow process; it takes three days for the gland to recover completely after a large secretion. Paralysis of the secretory fibres of the chorda tympani by atropine does not influence the rate of recovery. The recovery of the gland after extirpation of the superior cervical ganglion is accelerated. The experiments do not support the theory that the sympathetic nerve has any "trophic" influence on the submaxillary gland under normal conditions.—The Mutual Influence of Secretory Stimuli in the Submaxillary Gland of the Cat, by E. E. Goldenberg. In anæsthetised cats, two successive stimuli were applied to the gland itself, to its nerves, chorda, and sympathetic, with variation of the length of the interval of stimulation. Augmented secretion can be obtained by successive stimulation of the same or of the two secretory nerves, and an augmented vaso-motor effect—dilator or constrictor—can also be obtained by two successive stimulations of the same nerve.—P. M. Jurist and B. A. Rabinovitch find that the excitability of both sympathetic secretory and vaso-motor fibres of the submaxillary gland of the cat after section of the nerve in the neck is lost in from 41 to 48 hours.—The Nerve Fibre Constitution of the Nerves of the Eye, by M. Nakanishi. In the cat and sheep most of the post-ganglionic ciliary nerve fibres are somewhat larger (3·6–4·5μ) than the pre-ganglionic fibres (about 3μ). The nerves entering the ocular muscles have fibres of all sizes from 3μ to 17μ. The relative number of the fibres of different size is not very different, but the 3–6μ fibres are rather fewer than either the 6–5–10·5μ or 11–17μ fibres. The relative number of medium-sized fibres is greater than in the anterior roots of the spinal nerves. The greater part of the non-myelinated fibres of the sixth nerve run to the retractor bulbi; all the nerves entering the striated muscles have a few non-myelinated fibres; non-myelinated fibres also run to the eye by the long ciliary nerves; most of the non-myelinated fibres can be traced to blood-vessels.—Variations in the Sensibility to Pressure Pain Caused by Nerve Stimulation in Man, by R. C. Shawe.—The Effect of Insulin on the Oxygen and Carbon Dioxide Tensions in Air between the Skin and the Muscles, by J. Argyll Campbell and H. W. Dudley. Atmospheric air was injected under the skin of an unanæsthetised rabbit and left there until the CO_2- and O_2-tensions had come into equilibrium with the tensions of these gases in the tissue spaces. In the case of CO_2 this occurred in about an hour, the tension being at about 40 to 50 mm. Hg. The O_2-tension equilibrium was not established until 36 hours after, when the tension was 20–30 mm. Hg. Equilibrium once established the tensions usually remained fairly constant for one animal over long intervals of time—months. It was found that after subcutaneous injection of insulin in normal rabbits that the curve for O_2-tension in air between the skin and the muscles follows the blood-sugar curve; the effect appears to be localised, and is not due to constriction of blood-vessels. Insulin also causes an increase of CO_2-tension in the same region, which lasts as a rule only a couple of hours.—On the Blood Phosphate After Insulin Convulsions, by L. B. Winter and W. Smith. It is known that the inorganic blood phosphate is diminished as a result of injecting insulin into rabbits, and this fall also occurs in the treatment of diabetes mellitus in man by injection of insulin. Animals may be recovered from insulin convulsions by means of glandular extracts. The authors have made a careful study of the inorganic blood phosphates after insulin convulsions in rabbits. These animals can be recovered from convulsions by means of glucose, adrenalin, adrenalin and thyroid extract together, and pituitary extract. After adrenalin the inorganic phosphate usually regains the normal level quickly, but falls again. After pituitrin the effect is variable. After glucose the normal value is not regained for a considerable period.—Mitral Insufficiency, by D. T. Barry. The author has studied mitral lesions in the dog, using the heart-lung preparation, but this communication deals chiefly with a case of heart affection in the human subject. The paper is illustrated by some normal and abnormal optical records of the heart, and venous and arterial pulses are shown from human beings and from the heart-lung preparation of the dog. Records of mitral regurgitation in man offer evidence of leakage occurring in the early or so-called presphygmic period of systole. Those of artificial lesion in the dog afford similar evidence. The volume of fluid regurgitated is in some measure accountable for the time in which back-flow occurs, and this is especially so when the difference between auricular and ventricular pressures is marked. Some evidence is provided that the auriculoventricular valves are finally sealed as a result of the ventricular pressure. A mechanical explanation of the condition of pulsus alternans by alternating efficiency of the mitral valve is suggested without prejudice to the view that it may occur from inherent fluctuation of muscular function.—Some Variations of Capillary Diameter and Antidromic Action chiefly in the Web of the Frog's Foot, are recorded by Soroku Oinuma.—Other papers include the Interrelation of Parathyroids, Suprarenals, and Pancreas, by G. A. Clark, in which some interesting observations on the actions of guanidine on the blood-sugar in rabbits, the antagonism between it and calcium, and the results of parathyroid administration when given with guanidine or some time before. Three papers on muscular work—viz.: the Maximum Realisable Work of the Flexors of the Elbow, by T. E. Hansen and J. Lindhard; the Effect of Fatigue on the Relation between Work and Speed in Contraction of Human Arm Muscles, by A. V. Hill and others; on the Influence of Speed on the Mechanical Efficiency, by E. P. Cathcart and others. together with two papers on Renal Secretion—Secretion as a Factor in Elimination by the Bird's Kidney, by E. B. Mayrs; and Localisation of Excretion in the Uriniferous Tubule, by J. M. O'Connor and J. A. McGrath.

BRAIN. Vol. XLVI. Part 3.—The Pathology of the Parkinsonian Syndrome following Encephalitis Lethargica, with a note on the Occurrence of Calcification in this Disease, by Douglas McAlpine. The histological findings in two cases are described; subacute inflammatory changes and recent perivascular hæmorrhages were found. The substantial nigra was implicated in one but not in the other case. Calcification in the anterior part of the globus pallidus was found in six cases of encephalitis lethargica, in one case as early as the fourth day of the disease.—On Variations in the Form of Reflex Movement, notably the Babinski Plantar Response, under Different Degrees of Spasticity and under the Influence of Magnus and De Kleijn's Tonic Neck Reflex, by F. R. M. Walshe. In the presence of a high degree of extensor hypertonus the hip and knee components of the flexion reflex were reduced very considerably, while the Babinski plantar response was less affected. Rotation of the head towards the hemiplegic side, increasing hypertonus, leads to shortening of the extensor response or may even abolish it; this is rightly claimed to be a point of practical importance.—On Cerebellar Localisation, by Sven Ingvar. This is a valuable review of recent work together with a record of two original cases. The author divides the cerebellum into three lobes—anterior, middle, and posterior. The ponto-cerebellar fibres pass to the middle lobe, the spino-cerebellar and the vestibular fibres to the anterior and posterior lobes. A regional representation has been demonstrated only in the middle lobe, the anterior part of which is related to the upper limb and the posterior to the lower. The functions of the anterior and posterior lobes are related to the body as a whole and not to any special segment of it. The paper gives a good impression of the way in which the problem of the cerebellum has been attacked in recent years along the paths of anatomy, comparative anatomy, embryology, physiology, and pathology.—The Occurrence in Osteitis Deformans of Lesions of the Central Nervous System, with a Report of Four Cases, by W. G. Wyllie. In two cases the disease produced so great a narrowing of the spinal canal that a compression paraplegia resulted; this was relieved by laminectomy in one case. Optic atrophy without any other change in the fundi is recorded in two further cases.

Public Health Services.

MENTAL HOSPITALS SERVICE.

MANY important structural improvements, some now in progress and others to be undertaken during the present year, are referred to in the annual report for 1923 of the *City of London Mental Hospital, Dartford*. These include new verandahs, a dining hall for the staff, an additional ward for acute cases, an operating theatre, an X ray plant, and a laboratory. As in former years, parole has been granted on an extensive scale, no less than 86 patients being given outside parole, and 54 leave of absence for varying periods. Another interesting feature of the life of this hospital is the conduct of the church services; the choir and congregation are partly composed of visitors from outside, a circumstance naturally regarded as preventing patients from feeling that they are cut off from the general community. A further step has been taken in encouraging mixing of the sexes among the patients in the church, instead of placing the women on one side of the aisle and the men on the other. The malarial treatment of general paralysis has been tried in eight cases, and, although no definite conclusions as to its efficacy were arrived at, three of these patients have since been discharged. This treatment was also employed in 27 cases of dementia præcox. Some improvement was noted during the pyrexial stage, but "when this was terminated by quinine the patients relapsed into their former state." It will be extremely interesting if this treatment is found to influence any other disease than general paralysis, but the fact that syphilis and malaria are both due to protozoa, affords some sort of rational basis for its employment in general paralysis, whereas in other varieties of insanity the mere effect of fever per se offers the only hypothesis as to its possible action.

There are many mental hospital reports which consist almost entirely of statistics, but there is only one which consists solely of the medical superintendent's report, the feature to which the reader looks for insight into the working of an institution. This is the annual report of the *Royal Hospital, Morningside, Edinburgh*, and Prof. G. M. Robertson, in describing its work in 1923, deals, as usual, with a number of problems which are engaging the attention of the profession and of the public. Several changes have taken place or are contemplated at Morningside. The proposal that an out-patient clinic should be established there has been modified; in order that no prospective patient shall be deterred by an aversion for asylum associations, this clinic is to be established at the Royal Infirmary under the direction of Prof. Robertson, and a social worker is to be employed. If legal difficulties can be overcome, it is hoped to establish in the near future a psychopathic hospital for voluntary patients; this will be on the Morningside estate, but with a separate entrance, and otherwise distinct from the existing institution. The value of coöperation with the University is also illustrated in a new arrangement whereby in exchange for a grant towards a lectureship in neuro-pathology, the professor of pathology in the University will direct the work of the Morningside laboratory. A series of cases of general paralysis has been treated, with satisfactory immediate results, by malaria inoculation, and it is next proposed to treat this disease with tryparsamide, the General Medical Council having asked the hospital to investigate the utility of this drug. The recent decline in the admissions of general paralytics has been maintained, and Prof. Robertson offers an ingenious explanation of the fact that this decline has been greater among females than among males. Among the questions of more general interest treated in the report are criminal responsibility, the limitations of Christian Science and spiritual healing, the experience of hallucinations by sane persons, and the dangers of "spiritualism." In connexion with the latter, Prof. Robertson points out that not only are people made insane by spiritualistic practices, but undoubtedly the converse may take place, an individual may be drawn to spiritualism as a means of accounting for abnormal mental experiences which are being passed through. A vivid example of the former class, the "Monomania of Unseen Agency," is described, in which the patient having attempted by various means, and with no very serious purpose to "get into communication with the unseen," began to be tormented by voices, and eventually suffered from confirmed hallucinations of almost every sense. Such cases, which are not by any means rare, should be a warning of the danger which spiritualism involves for anyone with a latent tendency to nervous disorders. The hospital runs a journal of its own, and the "Morningside Mirror," several recent copies of which have reached us, maintains its high standard of topical and literary interest.

In the annual report for 1923 of the *Glengall Mental Hospital, Ayr*, the medical superintendent, Dr. G. Douglas McRae, again deplores the delay which commonly takes place before sending mental cases for treatment. Of the admissions in the year under review, only 16 per cent. of the men and 7 per cent. of the women arrived within three months of the onset of their illness, and in many cases the duration of the illness before admission was much longer. Apparently the euphemisms "neurasthenia" and "nervous breakdown" often embody the excuses offered by relatives for the delay in these cases. On the other hand, he deplores the certification of advanced senile dements, who not uncommonly die within a few weeks or months of admission. "It seems pitiable that such cases of senile dissolution cannot receive nursing attention in their own homes." A marked improvement in the average standard of physical health at the time of admission is greeted with less enthusiasm than might at first be expected, on the ground that "an unhealthy mind in a healthy body is found by experience to be a very incurable form of insanity." There is, however, "an unusually large proportion of decrepit and bed-ridden cases" in the hospital, and the death-rate from tuberculosis is more than doubled. No mention is made of the extent or existence of facilities for isolating these cases. A very pleasant innovation is a nine-hole golf course which has been laid out in the grounds during the year.

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 12TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely: Small-pox, 122; scarlet fever, 1522; diphtheria, 654; enteric fever, 44; pneumonia, 1853; puerperal fever, 43; cerebro-spinal fever, 7; acute poliomyelitis, 2; acute polio-encephalitis, 1; encephalitis lethargica, 206; dysentery, 6; ophthalmia neonatorum, 120. No cases of cholera, plague, or typhus fever were notified. The cases of encephalitis lethargica were notified in the following counties: London, 23; Chester, 5; Derby, 10; Durham, 6; Essex, 8; Gloucester, 9; Lancaster, 25; Middlesex, 4; Northumberland, 10; Nottingham, 4; Stafford, 5; Warwick, 30; Yorks, W.R., 47; and elsewhere in smaller number.

Deaths.—In the aggregate of great towns, the deaths from influenza fell from 403 to 316. In London the deaths from diphtheria fell to 6, and those from measles, which had been 62 in the preceding week, rose to 66 last week. The deaths from influenza in London further fell to 28 last week.

New Inventions.

TWO NEW SWAB FORCEPS.

Two patterns of forceps which I find very useful—one a spring swab forceps (Fig. 1) and the other bow-handled (Fig. 2)—have recently been made for me. Aided by an ordinary dressing forceps they are used to pick up and squeeze out moist pledgets. They have been designed primarily to replace the fingers when dressing wounds, obviating thereby (1) the necessity for gloves when doing this, and (2) the danger of contaminating the lotion by repeated immersions of the bare hand, as is so often done. At operations they are useful for manipulating mops or for picking up such vulnerable tissues as a loop of intestine or the appendix. For the latter purpose the gripping surface is best provided with wide grooves. The bow-handled forceps is provided with ratchets to enable a swab once gripped to be retained so that it may be laid aside and picked up again as the operation proceeds. The essential element in the spring swab forceps is the lightness of its spring, which should respond to the least touch and not tire the fingers at all. These forceps may well be made of rustless steel.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XVI.—MEDICAL SECRECY.

BY HUGH WOODS, M.D.,
GENERAL SECRETARY, LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

> "If ever you betray what you are entrusted with, you forfeit my malevolence for ever; and your being a simpleton shall be no excuse for your locality."
> —SHERIDAN, *The Rivals*, Act i., Scene 2.

IF a man promises to keep secret the information which is imparted to him, and fails to do so, he is rightly regarded as untrustworthy or dishonourable. Patients, when consulting their medical advisers, do not ask for a promise of secrecy, because it is understood that medical practitioners are, in any case, pledged to keep secret what comes to their knowledge through the practice of their profession. Were it not so, patients would no doubt make a rule of exacting a pledge of secrecy from their medical attendants beforehand. A medical practitioner must consequently be regarded as bound by an implied promise of secrecy unless he has definitely informed his patient beforehand that he will not accept this obligation. It is, however, rightly assumed that a patient is aware that his doctor is legally bound to report cases of infectious disease to the proper authorities, to give a certificate of the cause of death, and, in general, to give such information as he is by law required to give. Apart from legal compulsion, the obligation of secrecy is absolute, and is one which admits of no laxity.

Where Secrecy is Conditional.

The only circumstances under which any violation of the rule of secrecy should be contemplated are those which may sometimes occur when the maintenance of secrecy would allow a crime to be committed which could be prevented by a departure from the rule. In such a case the patient should first be definitely warned that secrecy will only be maintained if this can be done without the crime being committed. If this warning is disregarded, the medical adviser is placed in a very difficult position. The patient may repudiate altogether the intention which he has previously admitted, and, in the absence of clear legal evidence of such intention, the medical adviser may find himself charged with libel or slander of a very grave kind as a result of his departure from the rule of secrecy.

In Cases of Venereal Disease.—It has been contended that when a man, who is known by his medical adviser to be suffering from syphilis in an infectious stage, is about to marry, a warning ought to be given to the woman who might otherwise innocently contract the disease. The wickedness of such procedure should be plainly impressed upon the patient, but it is not the duty of the doctor to give information of his patient's condition, and the objections to his doing so outweigh the considerations which might lead him to try to prevent the marriage by disclosing what has come to his knowledge professionally. If such breach of secrecy were right and proper, it ought to be openly authorised by the rules of the medical profession; since otherwise a medical man when incurring serious risk from a sense of duty is prejudiced by an apparent breach of faith to his patient, who, under present circumstances, would certainly regard it as such, and not without reason. The objections to any refusal to observe secrecy in cases of the kind render it altogether inadvisable. A patient, who was capable of the conduct indicated, would consult someone—probably not medically qualified—who would have no scruples about keeping the matter secret, and patients, who would otherwise have been guided by their doctors as to the avoidance of risk, would also be afraid of taking into their confidence medical advisers whom they felt unable to trust. If a medical adviser is justified in divulging the fact that a patient has syphilis, why should he not give information when a patient is about to marry who would in his opinion not be likely to have healthy children, or is a drunkard, or otherwise objectionable? Obviously such procedure would soon bring a medical practitioner's career to an ignominious end, and do vastly more harm than good.

In Cases of Criminal Conduct.—It not infrequently comes to the knowledge of a medical man, in his practice, that a patient has been guilty of criminal conduct; and some would contend that he becomes to some degree an accessory if he fails to give information to the police. Called to attend a patient suffering from the results of criminally procured abortion, it may be said that secrecy on the part of the medical attendant tends to the encouragement of this offence; but so, to some extent, does his success in mitigating the consequent illness of the patient. If the doctor could not be trusted, the patient would try to deceive him, notwithstanding the grave danger to herself if she succeeded. In fact, cases do occur in which this happens even under present circumstances. It is justifiable, although not a definite duty, to urge the patient to give evidence voluntarily against a person who has procured abortion for her, but, without her free intelligent consent, her medical attendant should not betray the confidence reposed in him in order to check criminal practices of the kind.

In the Case of Death, the law does not permit secrecy, and it cannot be maintained. Even then it not uncommonly will happen that legal proof of criminal abortion will be wanting, and resentment will be aroused against the doctor for bringing discredit upon his deceased patient. Where death has not occurred a statement that abortion had been criminally induced, if not capable of strict legal proof, might involve the doctor in an action for damages for slander, or libel, and such action, if successful, would, in view of the betrayal of confidence involved, probably entail vindictive damages.

Information Desired by Interested Parties.

Employers, solicitors, insurance companies, and others frequently apply to medical practitioners for information about patients, for which they offer payment. Information should never be given without a patient's consent, or in the case of a deceased patient, that of the proper representative. An employer asks a doctor to see a man employed by him, and undertakes to pay the fee. He then asks for the doctor's opinion of the man's state of health, and it may thoughtlessly be given to him. If, as a result of this, the man is discharged, the action of the doctor will be strongly resented, and, if the diagnosis can be called in question, an action for damages may be the consequence. Even though the communication is privileged, there is risk of the protection thereby afforded being ineffective on the ground of legal "malice." Juries sometimes find that there was malice on strangely inadequate grounds, when their sympathies are with the plaintiff, as they often are in these cases. For instance, the medical officer of a friendly society forwarded to the friendly society a certificate implying that the ailment from which a patient was suffering arose from his misconduct. The patient was, by the rules of the friendly society, deprived of the payment which he would otherwise have received. He brought an action for damages, and the jury found, on very unsatisfactory medical evidence, that the doctor's diagnosis was wrong. The judge ruled that the certificate was a privileged communication, but the jury found that there was malice on the doctor's part, and damages were given against him. The evidence on which the jury found that there was malice was to the effect that the doctor and his patient had, several years previously, taken opposite sides in a controversy in a local newspaper. This showed how little trust can be safely placed in the protection afforded by privilege. To avoid the risk thus involved by giving a certificate that may cause loss or damage to a patient, the certificate should be handed to the patient, so that he can forward it or not as he chooses. If he does not forward the certificate, the medical practitioner is not responsible for any consequences arising from the absence of a certificate, and, if it is forwarded by the patient, the certifier has not published it to a third party, and therefore, even if it were a libel, no claim for damages could successfully be made against him.

The Safeguard of Habitual Reticence.

Where there is no apparent reason for secrecy, medical practitioners are apt to fall into the habit of giving information freely to relatives, friends, and employers about their patients' ailments. One serious consequence of such a habit is that when secrecy is obviously imperative the unwonted refusal of information may do the patient as much harm as the giving of it, by causing surmises as to the reason for unusual secrecy. There are many cases in which a doctor is placed in an awkward position, requiring considerable tact on his part if he is to avoid personal discredit or loss. A mistress asks the family doctor to see a servant-girl who is indisposed, and she expects to be told what the doctor thinks is the nature of the ailment. Should it happen that a disclosure of the diagnosis made would probably lead to the servant's dismissal, it would obviously be wrong to report the diagnosis to the mistress without the patient's consent, and silence, or refusal to give information, may be damaging both to the patient and the doctor. If strict secrecy had always been the rule of the medical attendant his position will be much less difficult, and he will simply refer the mistress to the patient to whom he has already given his opinion. Where the mistress ought to be informed of the patient's condition, the subject should be discussed with the patient, who should be advised to do what is right under the circumstances. Information should in no case be given to the mistress, or anyone else, without the patient's free consent, and care should be taken that proof of such consent is available, if it is acted on. In the case of lunatics, or children, information such as is needed for the proper care of a patient should be given to the persons in charge.

Professional Secrets in the Witness-Box.

It is to be regretted that the law in this country does not forbid a medical attendant to betray professional secrets in the witness-box. It is not sufficient that he should be at liberty to refuse to do so if he chooses, because if it were optional the refusal to give evidence might be regarded as implying that there was something which the patient wished to conceal, and it might consequently be prejudicial. In the present state of the law a medical man cannot be expected to expose himself to possible penalties by refusing to give evidence in violation of professional confidence when directed to do so by a judge, but the better part of the medical profession would support and approve of such refusal in suitable cases; and, if a firm stand were taken by the medical profession in the matter, it is unlikely that any prolonged conflict would be required to establish in the law courts a recognition of the duty of medical secrecy. It must, however, be remembered that it is the patients, and not their medical advisers, who would derive advantage from the prevention of the revelation of medical secrets in the witness-box. To patients suffering from venereal and other diseases it may be ruinous if their condition is made public to the world by the simple process of extracting information on the subject from their medical advisers in the witness-box. The dread of such a disaster undoubtedly affords an opportunity for blackmailing without resorting to any criminal procedure. The unwilling medical witness is a common feature of divorce proceedings, since his evidence, in addition to supporting the petition for divorce, will often do irreparable injury to the reputation of his patient. Doctors naturally dislike being used for such purposes, but it seems strange that the public allow themselves to be constantly victimised in this way when they have full power to put a stop to it. A medical man is much less likely to be subpœnaed as a witness if it is quite unknown to the solicitors concerned what his evidence will be, and it is sometimes his own fault when they are aware of it beforehand.

INCOME-TAX ALLOWANCE FOR MOTOR-CAR REPLACEMENT.

SEVERAL correspondents have asked for help in drawing up income-tax returns so as to obtain the allowance for motor-car replacement. Typical difficulties are the following:—

SIR,—I bought a car in 1921 for £365. It was a Crew Ford underslung Ford with an English body, the first car I had owned. A year later I sold this car for £95, and purchased a Morris Cowley for £314. I have now sold this Morris Cowley for £150 and am buying a Humber 11·4 h.p. for £460. I have never claimed income-tax allowance on the purchase of the Morris Cowley, although the Inspector of Taxes has consented to repay the difference between the £95 and £314, considering it as a replacement. But he quibbles over allowing income-tax reduction on the difference between the purchase price of the new Humber (£460) and the selling price of the Morris Cowley (£150) on the grounds of the increased capital outlay. In other words, he does not consider substituting a Morris Cowley by a Humber a "replacement," particularly as the present market price of the Morris Cowley is £198. I would be glad if you would let me know my position in this matter.

SIR,—I bought a second-hand Standard car 9·5 h.p. in August, 1921, for £337 10*s.*, and sold it in April, 1923, for £115. On the latter date I bought a new 12 h.p. Austin car for £460. To what relief of income-tax am I entitled ?

Where a motor-car is used for professional purposes, as was pointed out in a recent article,[1] a curious anomaly exists. The right to claim wear and tear is confined to traders and manufacturers, so that whilst a business man is allowed a deduction for depreciation of the car employed in his business, a doctor, whose practice equally necessitates the use of a car, cannot claim the same deduction. On the other hand, a claim may be put in for the renewal of a car, but only to the extent of the value replaced, less the amount received on sale or exchange. The question which now arises is: What is the replacement value which may be claimed ? Is it the original cost *or* the renewal cost, less amount received on sale ? The Royal Commission considered that the allowance for renewals should be calculated by reference to the cost price of the machinery replaced, thus putting it in the same position as the allowance for depreciation. But this proposal is regarded as the basis of legislation, while the actual practice at present is to give renewals strictly on the basis of the cost of such renewals. Applying these principles to the concrete case stated by our first correspondent, the allowance is calculated as follows, assuming that the new cars were similar to those sold :—

1922.—New car (Morris Cowley)	£314
Less sale Crew Ford	95
Allowance	£219
1924.—New car (Humber)	£460
Less sale Morris Cowley	150
Allowance	£310

If, as appears probable, the Humber was of superior type and value to the car displaced, the increased value would be disallowed as being an addition or improvement and not merely maintenance of the previous value. The same principles apply in other cases.

---

[1] THE LANCET, Jan. 12th, 1924, p. 81.

THE LANCET.

LONDON: SATURDAY, APRIL 26, 1924.

THE CURSE OF THE TROPICS.

IT is probable that there are few folk in this country who have not, at some time or other, felt the fascination of the tropics. Countless British boys have experienced it during the breathless perusal of tales of adventure, for those vast regions which stretch between Cancer and Capricorn have for long been realms of high romance. To those who love the study of Nature and who delight in superb scenery the call of the tropics is insistent, for where is Nature so bountiful, and where can more varied majestic and beautiful landscapes be found than within what is often called, not perhaps too correctly, the torrid zone? To the merchant adventurer the tropics have ever appealed as a rich field for exploitation, as a veritable El Dorado, and indeed much of the actual and potential wealth of the world lies in those lands of the sun. The sportsman looks upon many a tract of the tropics as a paradise; the missionary is lured to hot climates by his or her craving for change and adventure, coupled with a desire to carry a gospel message to benighted heathen; the invalid, fleeing from the rigours of a British winter, seeks either the sub-tropics or the tropics themselves, and revels in bright sunshine and an immunity from icy blasts and showers of sleet and snow. In the tropics the soldier and the sailor see service under guises new and strange but withal attractive—at least for a time, while the merchant seaman comes and goes in our argosies of commerce, linking the far-flung, tropical possessions of the Empire with the Homeland and with each other. Such is one aspect of the tropics and of tropical life. Another is to be found in the need of this country for the produce of those territories which have been explored and exploited by her sons throughout the centuries, many of which they have tamed and reclaimed, most of which they have benefited, and in all of which they have left their bones. The enormous importance of the tropical dependencies of Great Britain from the commercial standpoint will be manifest at the Empire Exhibition, and there also something will be seen of their inhabitants, of their scenery, of their history. The exhibit will form a token of their loyalty to the Mother Country, of their dependence upon her and her dependence upon them.

But there is yet another aspect, not the least important and, in some ways, the most interesting, which happily receives attention and which will surely attract attention within the precincts of Wembley. Housed in the British Government Building there is a Tropical Health Section, the chief features of which are described elsewhere. No one who visits this graphic display of tropical medicine and hygiene can fail to be impressed by it; but few, it is to be feared, will realise to the full what it signifies and what tragedy and romance lie behind it all. There is manifested the tragedy of millions of lives lost for lack of knowledge, of naval and military expeditions wrecked, of vast treasures wasted, of notable and promising enterprises abandoned. There is a tragic burden of inefficiency, sorrow, misery, and despair, tales of which are scattered through many books, and which has left its mark, not solely in the form of graves, throughout the length and breadth of the tropical world. There is much of tragedy in the shape of lost opportunities, in the strangling hold of vested interests, in the stupidity, folly, and pig-headedness, aye, and wickedness, of those who opposed progress, who were deaf to the claims of science, who did their best to set back the clock. On the other hand, there is an element of romance in the strivings of devoted men to solve the mysteries of tropical disease, in the astonishing results they achieved, in the marvels they revealed, in the many contests they had to wage with doubters and traducers. Again, there is abundance of romance in the application of the knowledge gained and the transformation effected by such application, in the war waged, not only against disease and death, but with human pride and ignorance, prejudice and selfishness. Altogether tropical medicine is an amazing business, and most of it has been crowded into the last 30 years. But it would be a mistake to view the exhibits at Wembley merely in the light of an historical pageant. The burden of which we have spoken still exists, doubtless infinitely lighter than of yore, but for all that pressing heavily on many of our tropical possessions. Blessed in many respects the tropics have their disabilities. From the European standpoint the climate is trying, exhausting, sometimes almost unbearable, there is often an acute sense of isolation; the surroundings are frequently irritating, monotony may make for melancholy, the molehill with marvellous celerity becomes the mountain. Yet, excepting possibly climate in some of its aspects, all these trials and troubles sink into insignificance compared with the presence of disease. Disease is the true curse of the tropics: it militates against their conquest by man and has in the past defeated him time and again. In the old records it is strange to read how men groped in darkness, attributing tropical maladies, as, for example, malaria and yellow fever, to all kinds of causes—miasmata from marshes, effluvia from decomposing material, atmospheric disturbances, and even to celestial displays like comets. It is, moreover, pitiful to note how, when someone more enterprising or enlightened than his fellows, a SUSRUTU, a RUSH, a NOTT, a BLAIR, a BEAUPERTHUY, a FINLAY, or a KING, advanced a theory which we now know approached the truth, little or no notice was taken of his hypothesis, and when it was not actually ridiculed it was soon relegated to the limbo of forgotten things.

These men were in advance of their times, and it was not until new conceptions on protozoology and entomology had been evolved, and the microscope and the laboratory had begun to take a serious part in the fray, that any real progress was forthcoming. Once, however, LAVERAN and MANSON had led the way, the path in respect of malaria was open for ROSS to commence his brilliant and unforgettable researches; open in one sense, but beset with difficulties and obstacles in another, for he, like others before and after him, was the victim of official stupidity and neglect. The Italians played their great part, and the mystery of malaria transmission was solved. As a direct result the Americans grappled with the problem of yellow fever, and with the loss of some valuable lives wrested the secret which "Yellow Jack" had for so long managed to conceal. But the Americans went farther. They realised and appreciated the great opportunity vouchsafed to them, and, fired by that idealism which so often spells success, they set out to obliterate the disease altogether.

What is more, they have well-nigh succeeded, and the burden of yellow fever has been almost lifted from the New World. Yet on the African West Coast the disease still lingers and flares out at intervals, while apathy and a false economy tolerate the presence of its mosquito vector. At the same time it may be admitted that the problem on the eastern side of the Atlantic is in some respects different to that upon the western, so that an equitable comparison cannot easily be drawn. Meanwhile malaria still remains the second or third great killing disease of the world, dysentery slays outright or makes miserable wrecks of men and women, cholera sweeps away the unwary, plague claims its victims in thousands and hampers commerce, ankylostomiasis saps the energy of native labour, leprosy makes pariahs and outcasts of hapless sufferers, and sleeping sickness, far from asleep, takes toll of the African negro. Yet in every instance we know the why and the wherefore of these maladies, and to a very large extent could and should extend our mastery over them. In many cases a great deal has been accomplished—how much no one can say who has not made a study of the past with its truly appalling records, who has not read of veritable armies of men disappearing as the result of epidemics, of thousands of young and promising lives cut short on the threshold of the tropics, of the crippled beings, a mere remnant of those who had sallied forth, returning from India and elsewhere with ruined constitutions, a burden to themselves and to their country. The wonder is that any survived, and that acquired immunity can be such a potent force as it has proved itself to be. It would, however, be a bad business if we had still to rely upon acquired immunity; and, though it will continue to play its part, its beneficent action must be reinforced by measures based on a sound knowledge of tropical pathology. In certain directions there is good cause for especial satisfaction. New light has been thrown upon plague by Norman White; leprosy, thanks to Sir Leonard Rogers, is to be attacked upon a scale never hitherto attempted, the parasites of ankylostomiasis and sleeping sickness are being countered by new and surprisingly effective remedies, leishmaniasis is controlled by tartar emetic, yaws has been conquered by the organic arsenicals and bismuth, and schistosomiasis has yielded to antimony and emetine.

So far so good, but in other directions the outlook is somewhat depressing. Malaria in many places still defies us, largely because we do not take it seriously and spend enough upon its suppression; dysentery in its chronic form remains an enigma as far as treatment goes; the epidemiology of cholera eludes us, while in many hygienic directions our tropical possessions lag behind the times and pay a corresponding penalty. Let us then welcome the Tropical Health Section at Wembley. It should excite interest and create enthusiasm. Not only does it furnish information regarding the cause, nature, and treatment of many tropical diseases, but it shows, by models and otherwise, how we have learned to safeguard the public health in those lands beyond the sea. In this all-important and humanitarian work men of our race and lineage have played a notable and a noble part, and it is fitting that in the great display of the Empire's resources there should be emphasised those disease factors which exercise a malign influence upon those resources and their exploitation. We welcome this record—a fascinating record—of what has been accomplished by the combined efforts of the clinician, the laboratory worker, and the hygienist.

RADIOGRAPHY OF THE RIGHT HYPOCHONDRIUM.

Of recent years much attention has been given to the diagnosis of affections of the upper abdomen from data obtained by the use of X rays. Whilst gastric diseases soon yielded to the systematic investigations of the radiographer, many difficulties prevented the development of a technique for demonstrating the presence of affections of the duodenum and gall-bladder. A stage has now been reached when, with a considerable degree of certainty, disease of these organs can be predicted on the results of radiography alone. This has been brought about particularly by the work of Cole, Case, George, and Leonard in America, and of Holland and Knox in this country. These observers concentrated their efforts upon the direct, as opposed to the indirect, signs relied upon almost exclusively by continental workers. Now, however, it is widely conceded that direct evidence is obtainable and extremely valuable. Yet in spite of the demonstration of such possibilities the inherent difficulties of the subject have prevented the rapid communication of the technique to radiographers in general. To take the duodenum first. It is not always possible to visualise this part of the alimentary canal after a barium meal by a simple antero-posterior exposure. The duodenum may be behind the gastric shadow, so that it can only be seen in a lateral or oblique view. The contrast meal remains for but a short time in the first part of the duodenum, from which it is expelled at intervals by a peristaltic contraction rapidly through the rest of this viscus. It thus happens that it is necessary to select the right moment to photograph the duodenal cap, whilst demonstration of the second and third parts is often a matter of chance. The choice of the right position and the appropriate time for the exposure is essential, but once this has been done the shadow of the duodenal bulb can afford much information. Irregular distortion, a niche or incisura may give clear evidence of duodenal ulceration, but two facts must be borne in mind: a duodenal ulcer may be present with no deformity of the cap; irregularities from periduodenitis may depend upon disease, not of the intestine itself, but of the neighbouring gall-bladder. There is considerable liability to error also if a proper filling of the duodenal bulb cannot be induced, for appearances almost exactly simulating those resulting from disease may obtrude themselves. When the barium delays in the second and third parts of the duodenum, the chronic ileus, described in this country by Wilkie as due to compression by the superior mesenteric artery, is nearly always present. Gall-bladder affections afford even greater problems when their demonstration by X rays is essayed. The density of gall-stones is so nearly that of their surroundings that a nicety of adjustment of the penetration of the rays to the case in question is of prime importance. With care in this respect, the use of intensifying screens and rapid exposures, a considerable proportion of gall-stones will throw recognisable shadows. But not only can disease of the gall-bladder be detected in this way; it also frequently gives evidence by altering the contour of the duodenum or stomach or by fixing the upper jejunum or transverse colon. By taking account of both direct and indirect signs in 128 cases, A. W. George and R. D. Leonard were able to arrive at a correct diagnosis of gall-bladder disease in 88·4 per cent., a nearly similar proportion of success being also claimed by Pierre Duval. It is therefore clear that a new era of exactitude in the diagnosis of affections of the gall-bladder and duodenum has arrived, and it only remains for spread of the knowledge to render these methods available to the general surgeon. For though these researches have now been proceeding for some years, it must be conceded that in the case of gall-bladder disease, at any rate, the assistance afforded by radiography in this country can only be described as meagre and inexact, except in the hands of a few experts.

◆

PUBLIC HEALTH SERVICE IN THE UNITED STATES.

To appreciate the differences between the public health services of the United States of America and our own Ministry of Health two considerations have to be borne in mind. The first is that the United States is a comparatively new country with a population about double that of the United Kingdom, occupying an area of nearly 4,000,000 square miles instead of something over 120,000, and confronted with all our diseases and a great many besides. In the second place, the Federal Public Health Service has passed through an evolution very different from that of our Ministry of Health. It began over a century ago as the Marine Hospital Service, to provide treatment for sick and disabled seamen. The problem of protecting the States as a combined whole from the introduction of disease from without and of the protection of one State from another led to the establishment of foreign and inter-State quarantine departments. The experience thus gained by the Service led to its aid being called in by the various States and to the establishment of a research department, which is at present investigating practically every public health problem. That there is no parallel between the system of administration which obtains in Great Britain and that of America was emphasised in a recent Chadwick Lecture by Dr. CHARLES PORTER, who, under the health officers' interchange scheme of the Health Section of the League of Nations, visited the United States to study the public health problems of that country. Dr. PORTER comments on the American practice of centralising power. The President of the United States is the executive; the cabinet is his; he appoints the ministers, who are responsible to him and not to the elected body. He commissions all officers, including the U.S. Public Health Service officers, who are classed as military officers and have ranks corresponding to those in the Army Medical Service—Surgeon-General, and so on—and wear a uniform as and when it appears proper, on port and quarantine work, for example. In each of the individual States there is a chief executive, the Governor, who appoints the chief officers. In cities, in general, the mayor is the chief executive, the chief officers being his. In the health department the chief health officer, usually known as the Commissioner of Health, is the executive and he commonly makes the appointments to the subsidiary positions.

The great work carried out by the Federal Public Health Service is well shown in the report of Surgeon-General H. S. CUMMING for the year 1923.[1] In addition to the divisions for marine hospitals, foreign quarantine, inter-State quarantine, and research, there are divisions for sanitary reports and statistics, for venereal diseases and of personnel and accounts, each of the seven divisions being administered by an assistant surgeon-general. At the beginning of the year, the report states, there were about 200 commissioned medical officers on the regular corps, graded as senior surgeons, passed assistant surgeons, and assistant surgeons, in addition to nearly 1000 reserve commissioned officers on active duty. The total medical, scientific, and general staff at the end of the year numbered 9420. Members of this staff are loaned out on application to the various States and counties for conducting intensive sanitary surveys, for investigating various disease problems, for instituting local public health services in primitive regions at present lacking in such organisations, for setting in motion schemes of school medical inspection, and so on. All this pioneer work is largely helped by Federal grants-in-aid and by funds supplied by the International Health Board, formerly the Rockefeller Commission. General CUMMING reports that health conditions generally were as satisfactory as in recent years. Two charts show the wonderful decline in the mortality from typhoid fever and the steady improvement in the tuberculosis mortality since 1900 in the original registration States. The improvement in tuberculosis was interrupted in 1917 and 1918; these were also the worst years of the retrogression which occurred in England and Wales during the war. The venereal diseases division records that the occurrence of new cases was noticeably less in the year under review. A sharp outbreak of yellow fever in Colombia and the evidence of a high mosquito index in certain seaports in tropical America made it necessary to impose more stringent quarantine restrictions. On the other hand, the recognition of the Government of Mexico has been followed by improved sanitary conditions in Mexican ports and it has been made possible to remove some of the more stringent restrictions. As there has been no epidemic of yellow fever in the U.S.A. since 1905, there is now a very small percentage of immune persons in the Southern States. The Mexican border country is badly infested with the stegomyia mosquito, and a rigid watch has to be kept by the quarantine division along the land frontier to prevent clandestine crossing and the introduction not only of yellow fever, but also of small-pox and typhus. Human and rodent plague appear to have been eliminated, but the infection still remains in ground squirrels in California. General CUMMING emphasises the value of the medical officers of the service stationed in European, Asiatic, and Spanish-American ports, not only for the protection of the U.S.A., but for the prevention of delays to shipping when America is reached. Such officers will form the nucleus of the organisation required when Congress passes the much-needed laws providing for the examination of immigrants before embarkation for America.

Rural sanitation has been carefully investigated and the results show that the fundamental need throughout the rural districts of the United States is the establishment of efficient local whole-time service of public health officials. Valuable anti-malarial investigations have been made as to the Paris-green method for the control of mosquito breeding in ponds and the creosote method for repelling mosquitoes from dwellings. Some idea of the larger activities of the division of scientific research may be gleaned from the following list of subjects, to each one of which an expert and a group of trained workers has been assigned: child hygiene, industrial hygiene, stream pollution, epidemiology and statistics, malaria and sewage disposal. Among the individual diseases studied have been cancer, clonorchiasis, diphtheria, dengue fever, Malta fever, pellagra, tuberculosis, typhoid fever, yellow fever, leprosy, Rocky Mountain spotted fever, and food poisoning; and among other topics mental hygiene, milk and public health administration. The functions of the U.S.A. Public Health Service are advisory and consultative rather than supervisory in relation to the various States, and the aim is to stimulate public health activity and to coöperate with the various State, county, and urban health services. It must, we fear, be admitted that the interests of public health hold a higher place in the minds of the people, or at any rate are more enthusiastically advanced, across the Atlantic than they are in this country. As an instance of this we might quote Dr. PORTER's remarks on milk control. Milk control, he stated, was left almost entirely to individual States, and there was little doubt that, owing mainly to a determination on the part of both local authorities and consumers to have a pure and clean milk-supply, and to coöperation by all parties, including producers, railroad and distributing companies, the conditions in the States were better than in this country, and the American consumer got a safer article. Factors contributing to this achievement were: propaganda, the driving of milk production into the hands of the farmer who was exclusively a dairy farmer, pasteurisation (about 98 per cent. of the milk sold in most cities is so treated), and bottling. Decrease amongst American children in tuberculosis of the bones and glands may be attributed largely to this improvement in the milk-supply. Public health workers in whatever sphere may draw instruction and stimulus from General Cumming's report.

Annotations.

"Ne quid nimis."

FOREIGN BODIES IN THE BRONCHI.

We publish with this issue the third Lumleian Lecture by Dr. Thomas McCrae, of Philadelphia, professor of medicine at the Jefferson College, Philadelphia. Prof. McCrae has chosen for his lectures a unique subject, and in doing so he has grasped a unique opportunity. Nowhere else in the world has been collected such a series of cases of foreign bodies in the bronchi, and it is to the genius of Chevalier Jackson that the Jefferson College owes this proud distinction and a large group of patients their relief. More than 1300 cases have presented themselves with this dangerous and most distressing condition, often after other surgeons had attempted and failed to give them relief. Jackson has never once failed to remove the foreign body, usually in a few seconds and always by the bronchoscope. Probably only those who have seen Jackson at work can appreciate his uncanny skill, but all those who have read his book will realise the debt owed to him by humanity and by surgeons all over the world. They will appreciate at their true value the laborious care upon which such skill has been founded, and the generosity which has revealed to others the steps by which it was built up. Some of them, gifted with unusual common sense, will pay the highest possible compliment to the author by following his methods and emulating his skill. With admirable breadth of outlook Prof. McCrae has given to these cases a far wider meaning than that of a mere mechanical accident. The impaction of foreign bodies in the bronchi is rapidly followed by a series of profound pathological changes in the lungs, and from these pathological changes and their clinical manifestations lessons have been drawn of deep significance for both the physician and the surgeon. The lectures should be studied with care by all who are interested in lung conditions. They arouse an uneasy feeling that some of the cases which have baffled all our efforts at diagnosis and resisted all attempts at cure may perhaps be due not to chance infections but to the inspiration of gross foreign bodies. They open up a definite line of progress demanding the close coöperation of medical and surgical skill.

EPIDEMIC GANGRENE OF THE VULVA.

Dr. W. K. Stephansky[1] describes an epidemic of gangrene of the external genitals in little girls which occurred in a hospital at Odessa from December, 1922, to June, 1923. The disease had an acute onset and course accompanied with a high temperature. The morbid process usually started on the labia majora, less frequently in the neighbourhood of the anus or skin of the perineum. The first signs were redness, œdema, and pain in the labia, and in a few days small ulcers developed, which rapidly increased in size, involving the labia minora, clitoris, vestibulum, vaginal mucous membrane, perineum, and lower part of the rectal mucous membrane. In another three or four days moist gangrene set in. Aggravation of the general condition then ensued, and death took place in two to seven days with symptoms of septicæmia and toxæmia. The lesions were usually, but not always, symmetrical. The mortality was high. Of nine cases specially studied by Dr. Stephansky seven died. The disease generally occurred during or after measles, scarlet fever, or whooping-cough, but in one case the child had had no previous disease. All the children at the time of the attack were in a satisfactory general condition and well nourished. The following considerations show that there are no grounds for regarding the condition as identical with cancrum oris. In the first place, cancrum oris does not occur in previously healthy children, but only in those that are debilitated. Secondly, the onset is slow and insidious and all acute inflammatory phenomena, including high temperature such as were present in this outbreak, are absent. Thirdly, cancrum oris is almost always unilateral. Fourthly, in Dr. Stephansky's cases, the gangrene was superficial and destroyed only the skin and subcutaneous tissue, whereas cancrum oris extended not only superficially but deeply. No complete bacteriological examination was made, but smears of the necrotic areas showed fusiform bacilli and spirilla in all the cases. Diphtheria bacilli, which are frequently present in cancrum oris, were not found. Cultures of the blood on agar and broth, which were made in one case, proved sterile. Dr. Stephansky concludes that the condition described by him is not identical with cancrum oris, but is rather an acute epidemic disease sui generis, and possibly a new nosological entity.

TRANSIENT OPACITIES IN THE LENS.

Is it possible for slight opacities in the crystalline lens ever to disappear? Do they always tend to progress to the formation of a cataract requiring operation? To the latter of these questions every experienced ophthalmic surgeon will answer in the negative. To the former the answer will be by no means so unanimous. Many will tell us that as a matter of experience early lens opacities have disappeared, and some will cite cases in which, whether or not as the result of some special treatment, not only have the opacities disappeared, but sight has been materially improved. The article which we published on April 5th by Mr. Inglis Taylor is a remarkable case in point. He claims to have improved the vision in one or both eyes of some six or seven patients with cortical cataract, from 6/24 or worse to nearly, or quite, normal in the course of a few months' treatment by the external application to the eye of an ointment composed of a compound of calcium and iodine. This treatment is recommended by the French ophthalmologist Dor, and is based on the assumption that cataract is due to a hydration of the lens caused by the action of hydrating ferments in the blood. Whether this is true in all cases must be doubtful, but that the idea is fruitful and that the treatment has been efficacious in some cases seems to be proved by the details of Mr. Taylor's cases. The matter is one of great importance in which we need much further knowledge, both on the pathological and on the clinical side.

VARIATIONS IN THE SENSIBILITY TO PRESSURE PAIN.

By stimulating the median nerve with faradic currents through electrodes—one placed about four inches above the wrist and the other at the wrist, and applying increasing pressure on the thenar eminence by the application of weights 6–8–10 kg.—the pressure pain threshold being determined by an æsthesiometer, R. C. Shawe[1] finds that weak faradic stimulation of the median nerve, which caused a tingling sensation only, causes a marked lowering of the threshold of both cutaneous and deep receptors. This is accompanied by cutaneous flushing in the area of the hand supplied by the median, being especially noticeable in the index finger and thenar eminence. Very strong faradic stimulation, which could only be borne for a moment or two and evoked vigorous muscular contractions, raises the threshold in both cutaneous and deep receptors. It is accompanied by marked vaso-constriction in the palmar distribution of the median. The cutaneous receptors were excluded when necessary by freezing the skin with ethyl chloride. Faradic stimulation of the median nerve of a degree intermediate to the above caused a lowering of the threshold in the cutaneous receptors only. The changes were found to occur even if the circulation had been excluded for five to eight minutes, and therefore vascular change cannot be held to explain the sensory variation. Nor can changes in conductivity in the nerve fibres be held responsible for these results, because although strong currents may decrease conductivity, weak currents are not known to increase it. Observations on the contralateral side to that stimulated showed that during weak nerve stimulation there was a corresponding lowering of the threshold in the median and ulnar areas, which in some cases was associated with a flushing in the thenar region of the side stimulated and the opposite side. During very strong faradic stimulation the threshold was raised in both ulnar and median areas of the opposite side to that stimulated. The author concludes that the variations in the threshold of pressure pain caused by nerve stimulation are due principally to changes in the nerve cells with which the afferent fibres are connected.

THE MEANING OF FEVER.

LONG before the introduction of the clinical thermometer the meaning of fever was one of the most intriguing problems exercising the mind of the physician, and even when it became possible to measure degrees of pyrexia with accuracy but little light was thrown upon the matter. For many years a heightened temperature was regarded as evil in itself—very much as a heightened blood pressure quite usually is now—and in the treatment of febrile conditions the main line of attack was directed towards its reduction. Experience of antipyretic drugs led to some doubts as to the actual benefit to be expected from a mere lowering of temperature, and the pioneer experimental work of Rolly and Meltzer[1] showed that in infectious conditions some degree of pyrexia was certainly beneficial; the animals which they kept at fever heat were able to withstand infections fatal to normal controls. The light-hearted exhibition of antipyretics does not now hold a place in therapeusis, nor is the degree of fever looked upon to any great extent as an index to the gravity of the condition; none the less the why and wherefore of fever remains almost as much a mystery as ever.

Some little light has been thrown upon at least one aspect of the subject by Dr. Oliver Heath[2] in two communications recently made to the Royal Society of Medicine. Working partly upon himself with typhoid vaccines and partly upon typhoid patients, Dr. Heath has been able to obtain results indicating in a very clear and unequivocal manner that the course of fever runs parallel to the reduction below normal of antibody in the blood. Thus, on administering subcutaneously to himself 2000 million killed typhoid bacilli, he found that a rise of temperature to 100° F. was synchronous with a very considerable drop in the bactericidal power of his blood; the return of the temperature to normal on the day following the injection was associated with a restoration of the normal bactericidal power. Inoculation of doses of dead typhoid bacilli on ten successive days likewise produced irregular pyrexia, associated when the dose was sufficiently large with a demonstrable fall in the bactericidal titre of the serum; as in clinical typhoid fever there was no marked rise above the previous level of either the bactericidal or agglutinating power of the serum until about the tenth day. Dr. Heath suggests that an intensification of the experiment, by increasing the size and frequency of the doses, would have resulted in a continuous supernormal temperature and subnormal antibody titre, a condition which he believes to hold during the early days of a typhoid infection.

Numerous other observations are recorded, all going to show that fever is always associated with a reduction below normal of antibody in the blood. This, in itself, is a valuable observation. Dr. Heath interprets his evidence to mean that this reduction of circulating antibody is the actual cause of fever, and that the heightened temperature may be looked upon as in the nature of a systemic reflex designed to speed up the production of more antibody to replace that used up. The teleological attitude in pathology is beset with pitfalls, but on the evidence Dr. Heath seems justified when he recommends that the use of antipyretic drugs for the cure of fever should be discontinued.

PERISTALSIS AND MENTAL DISORDER.

IN the current issue of the *British Journal of Radiology* appears a short record by Drs. R. V. Stanford, Edwin Goodall, and Robert Knox of barium meal findings in 24 cases of mental disorder. The majority were recent cases and of a depressed type. As in a previous series published by these authors, the common findings were ptosis of the transverse colon, spastic contraction of the large bowel, and general stasis in the lower part of the intestinal tract. It is disappointing to find that the authors do not themselves comment on or analyse their results. Are these conditions of the intestinal tract to be regarded as a factor in the causation of insanity, or are they merely symptomatic? This appears to be a difficulty which would still have to be faced, even were a really characteristic abnormality demonstrable in every case of a certain type of insanity. For example, it might be asked: Is the patient melancholic because he is constipated, or is he constipated because he has melancholia? In a future communication from Cardiff Mental Hospital some answer to this question will be welcome. To return to the particular radiological findings, the abnormalities noted cannot be called characteristic; anyone familiar with X ray reports knows that ptosis and stasis are unhappily common in subjects whose sanity has never been in question.

ARTIFICIAL PNEUMOTHORAX STATISTICS.

IT is doubtful if the combined statistical evidence of many workers is as valuable as that of a single worker or institution, even if the figures of the latter are comparatively small. But on behalf of pooled statistics it may be claimed that individual lack of judgment and excess of enthusiasm are less likely to obscure the issue than when we have to depend on one worker for all our information. The problem is much the same as that of choosing a milk-supply from one cow or a large herd; if the one cow be diseased, it would be better for the consumer if he drew his milk-supply from a large herd with only one or two diseased cattle. A good sample of the large herd, or pooled statistics, is to be found in a paper by Dr. H. Maendl, of Grimmenstein,[1] who has collected the experiences of his fellow workers in much the same way that Dr. L. S. T. Burrell and Dr. A. S. MacNalty collected, under the auspices of the Medical Research Council, the work done in this country on artificial pneumothorax. Dr. Maendl addressed a questionnaire to 180 specialists and hospitals in Germany, Austria, Czecho-Slovakia, and Switzerland, and he obtained answers and statistically suitable information from 29 doctors. He was thus able to add more than 1000 cases to his own not inconsiderable material of 300 cases, and of the total thus obtained there were 1330 cases in which the treatment had been completed, the pneumothorax having been started 2 to 12 years earlier. With regard to the permanent successes achieved, there were 784 cases in which information on this point was obtained, and among them there were 524, or 66 per cent., in which the improvement effected had been lasting. It was so in 49 per cent. of 172 of Dr. Maendl's own cases. With regard to the significance of a pleural effusion complicating an artificial pneumothorax, he shares with Muralt and Koeniger the opinion that such an effusion may be a sign of good prognosis. Of 70 patients who were still alive from 2 to 12 years after the induction of a pneumothorax, 38, or 54 per cent., had developed a pleural effusion, whereas of 76 patients who had died only 28, or 37 per cent., had developed such an effusion while the pneumothorax still existed. Of 15 patients who had achieved clinical recovery, maintained for 2 to 10 years, as many as 11, or 73 per cent., had developed a pleural effusion. If a pleural effusion is really as beneficial as these statistics suggest, it would be natural to provoke such effusions artificially—and nothing would be easier with the help of a little tincture of iodine or other irritant—in the course of lung collapse treatment. But the case for such a procedure would have to be made out much more convincingly than it has been at present. It is satisfactory to note that there were only 15 cases of gas embolism, none of which terminated fatally, among the cases collected by Dr. Maendl.

MEDICAL PRACTICE BY FOREIGNERS IN BERLIN.

THE financial circumstances of medical practitioners within the German Republic are not at present so happy that free competition by foreigners is regarded with equanimity. As it stands, German law does not prevent foreign medical men from settling in Germany nor prohibit them from practising there; but the stipulation is made that they should not use any title identical with that of a duly registered practitioner or closely resembling it. Before the war the actual number of foreign practitioners in Germany not possessing German qualifications was insignificant, the foreign colonies in the country being of modest size and apt to consult the German practitioner. This condition was totally changed after the Russian revolution, when Germany—and Berlin in particular—was overcrowded with Russians who preferred to live outside their national jurisdiction. In certain quarters of Berlin at the present time more Russian than German may be heard spoken, and Russian shops, theatres, libraries, restaurants, and journals have sprung up in large numbers. It is stated that about 100 Russian medical men have settled in Berlin and practise among the large Russian colony there. A recent letter addressed to the *Berliner Aerzteblatt*, the official organ of the Berlin Medical Chamber, called attention to the fact that several Russian medical men in Berlin had private clinics of their own and were operating there with the assistance of registered German medical men. The writer suggested that Russian doctors were obtaining permission from the authorities to reside in Berlin on the plea of being political refugees. The Chamber, having approached the Government, was informed that no special residential facilities had been granted to foreign medical men, but that in several cases German doctors had let off part of their flats to Russian medical men as consulting-rooms. Further investigation was promised. In the meantime the Berlin medical profession is losing a great part of its pre-war income owing to the nearly total loss of Russian patients. Before the war these patients, flocking home from the western spas and health resorts, were wont to sojourn in Berlin to consult specialists there, whereas now they are permanently settled, they prefer to consult their own countrymen. The position is one which demands sympathetic handling.

INQUIRY INTO NITROUS OXIDE GAS.

IN view of the need for more accurate knowledge of the modes of action of various anæsthetic agents and of the impurities that may be associated with them, the Medical Research Council and the Anæsthetics Section of the Royal Society of Medicine have appointed an Anæsthetics Committee to initiate and direct investigations. The following have already undertaken to serve in this way: Dr. J. Blomfield (chairman), Dr. H. H. Dale, F.R.S., Prof. F. G. Donnan, F.R.S., Dr. C. F. Hadfield (secretary), Prof. M. S. Pembrey, F.R.S., Dr. F. E. Shipway. Among other subjects of study an immediate investigation is to be made into the nature and frequency of impurities that may occur in nitrous oxide gas. Nitrous oxide is now used for operations of considerable duration, so that impurities likely to have small effect during brief inhalation might be seriously toxic after prolonged use. At present there is no generally recognised standard of purity for nitrous oxide; it is not included in the British Pharmacopœia and is not subject to official tests. The nitrous oxide manufactured by the various British firms that supply it is of the highest quality, but from time to time reports of somewhat indefinite nature appear to show that toxic effects have been caused by the administration of what is generally briefly known as "gas." The suggestion that this toxicity may be due to some impurity in the nitrous oxide calls for examination, and the Committee are seeking any relevant information. It is requested that anæsthetists who can supply evidence of this kind in detail, and if possible the cylinder to which it relates containing any remaining gas, will communicate with the hon. secretary of the committee, Dr. Charles F. Hadfield, 47, Queen Anne-street, W. 1.

CARCINOMA IN A DIVERTICULUM OF THE BLADDER.

AT a recent meeting of the Brooklyn Urological Society, Dr. Augustus Harris, who reported an illustrative case,[1] remarked that the occurrence of carcinoma in a diverticulum of the bladder was extremely rare. Apart from about six cases in which the condition was not discovered until the autopsy, he had been unable to find a record of a single case. His own patient was a man aged 63, who had had gonorrhœa 25 years previously, and at the age of 62 had had an attack of hæmaturia for a few days, accompanied by retention for one day. Nine months later he began to suffer from intermittent hæmaturia, slowness in starting the act, and increased frequency of micturition. There was no pain, dribbling, or nocturia. He was rather pale and had lost weight. Vesical malignancy was suspected, and examination showed the presence of a dense filiform stricture in the bulbous urethra. There were 5 oz. of residual urine. The stricture was gradually dilated until, after eight weeks' time, full-sized sounds could be passed. Cystoscopy then showed a considerably inflamed and trabeculated bladder, and 1½ inches above the right ureteric orifice the puckered opening of a diverticulum. The bladder was injected with sodium bromide solution and a cystogram taken, which revealed a large sac with a capacity about half that of the bladder. On opening the bladder the tumour was found to be inoperable, and cystostomy was performed. Death took place seven months after the operation. There was no autopsy. After the account of this case had been written an article appeared in the January number of *Surgery, Gynecology, and Obstetrics* by Judd and Scholl, who, in a series of 133 cases of diverticulum of the bladder, reported four with carcinoma, all of which were diagnosed cystoscopically by the appearance of part of the growth at the orifice of the sac. In three the tumour and sac were resected completely, while in the fourth radium was employed. Three died shortly after the operation, and one lived for two years. In six other cases carcinoma of the bladder was associated with a diverticulum.

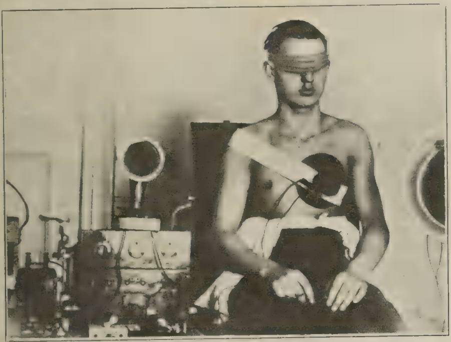
BROADCASTING HEART SOUNDS.

AT a meeting of the Bristol Medico-Chirurgical Society held on April 9th a paper was read by Dr. Carey F. Coombs and Dr. C. K. Herapath on auricular failure. This was followed by a discussion, and during the evening an experiment in "broadcasting" heart sounds was made, which if not new to this country, was at least sufficiently unusual to be of more than local interest. The experiment was carried out by Mr. Arthur Mitchell, of Clifton, who was introduced to the meeting by Prof. F. H. Edgeworth. The apparatus used was a sensitive microphone applied over the heart of a person in an adjoining room, and connected to a suitable transformer. This was then amplified by four wireless valves and reproduced through a loud speaker to the audience at the meeting. The first case was that of a normal heart, and the second, one with total arrhythmia. In both instances sounds corresponding to heart beats could be heard clearly all over the room, the irregularity in the second case being strikingly demonstrated. The improvement and perfection of such a method as this offers infinite possibilities for teaching in the future. The accompanying illustration, for which we are indebted to the Sport and General Press Agency, was taken at the clinic of Dr. Leo Jacobsohn, of Charlottenburg, who has also succeeded in amplifying the beats of the human heart so that they are audible in a large hall.



THE NATURE OF "BLOOD" CYSTS.

THE so-called blood cyst of the ovary has long been recognised by gynæcologists the world over; it is usually regarded as being produced by failure to rupture on the part of a Graafian follicle. Probably many such cysts do originate in this way, but recent work by Dr. John A. Sampson,[1] of Albany, N.Y., suggests that many have another and much more interesting mode of development. These cysts attain to their greatest size on the ovary, but Dr. Sampson, in the course of a long series of major gynæcological operations, observed smaller but otherwise similar cysts occurring in various sites upon the pelvic peritoneum. Histological examination showed that both the ovarian blood cysts and those occurring elsewhere possessed an epithelial lining closely resembling the uterine endometrium. Observation of the uterus during operations convinced Dr. Sampson that it was no unusual thing for menstrual blood to regurgitate through the Fallopian tubes into the peritoneal cavity, and actual experiment showed that very little manipulation of the uterus sufficed to bring about the same result after operations upon the endometrium. These observations led Dr. Sampson to believe that blood cysts both of the ovary and elsewhere within the pelvis may arise by implantation of fragments of endometrium escaping through the Fallopian tubes. He was able, moreover, to obtain evidence for belief that what holds for normal holds also for malignant uterine epithelium, and on the strength of this he advises certain obvious modifications, such as a preliminary ligation of the Fallopian tubes, in the performance of hysterectomy for malignant conditions of the uterus. Apart, however, from immediate practical considerations, Dr. Sampson's observations possess a wide general interest. He believes on good evidence that the endometrial implants grow more readily upon the ovary than elsewhere, and that the implants on the pelvic peritoneum are usually secondary to primary ovarian grafts. In the light of the work of Drew[2] on growth-producing substances, recently reported in THE LANCET, this indication of the presence of such a substance in the ovary is of particular interest; the invasiveness of some of these implants, even while clinically benign, gives food for thought. Even more intriguing is the suggestion—it is no more than a suggestion, for the evidence on this point is by no means conclusive—that implants originally benign may undergo malignant change in the presence of such a change in the parent uterine endometrium. Experimental evidence strongly in support of Dr. Sampson's views on the ætiology of the blood cysts has been produced by Dr. Victor C. Jacobson,[3] of the Albany Medical College, working upon rabbits.

THE OPHTHALMIC HOSPITALS OF EGYPT.

THE publication of the usual annual report on the Ophthalmic Hospitals of Egypt for 1922 having been delayed, an abstract of it has been printed privately by Mr. A. F. MacCallan, C.B.E., F.R.C.S., who recently vacated the post of Director of the Ophthalmic Section of the Department of Public Health. Mr. MacCallan held this post for 20 years, during which the organisation of a system of special hospitals proceeded hand in hand with that of a definite school of ophthalmology based on the administrative scheme of the Royal London Ophthalmic Hospital. The 23 existing ophthalmic hospital units situated in the capital towns of the 14 provinces are staffed by Egyptian surgeons, who, after obtaining their diplomas at the Government Medical School, go through a course of instruction at the Giza Hospital and Ophthalmic Laboratory in the suburbs of Cairo, lasting for a minimum period of two years. For some six years all Mr. MacCallan's assistants have been Egyptians, but it must not be forgotten that in the early years the help of other British surgeons was utilised in the initiation of hospital and laboratory courses of instruction. These were Dr. L. S. Miller, of Hobart, Tasmania, Dr. G. H. McLaren, of Montreal, Canada, Dr. E. V. Oulton, of Brighton, Dr. R. G. Waddy, now Professor of Ophthalmology at Sydney, and Dr. J. B. Horgan, of Cork.

The origin of the ophthalmic campaign in Egypt was the liberality of Sir Ernest Cassel in placing under the trusteeship of Lord Cromer, and thereafter under that of the High Commissioner for the time being, a sum of £40,000, the interest of which was to be used for the ophthalmic needs of Egypt. The initial step in carrying out the wishes of the benefactor was taken by obtaining the services of Mr. MacCallan, then working as chief clinical assistant at the Royal London Ophthalmic Hospital, to organise a travelling ophthalmic hospital at which ophthalmic instruction could be given. From this beginning in 1903 has arisen an ophthalmic system consisting of five completely equipped travelling hospitals under canvas, 16 specially designed and built permanent hospitals, and two ophthalmic departments attached to existing general hospitals. Readers of THE LANCET will recall many references to the work of the travelling units. The general administration, the clerical routine, and the clinical work of these hospitals are carried out according to a code of regulations which has the confidence of the staff. As each hospital has two surgeons, a clerk, and a steward, as well as highly skilled hospital attendants, there is an ample staff to cope with the patients; as many as 500 a day attend the out-patient department at certain periods of the year. Each hospital has a number of beds varying from 16 to 30. The higher administration consists of a director, a pathologist, and three inspecting surgeons, former pupils of Mr. MacCallan and appointed by him. There is also a carefully selected and highly efficient clerical staff at headquarters in Cairo, so that there is every reason to believe that the work will continue, provided that the administration remains strong, as well as sympathetic. A large part of the success obtained may be attributed to the fact that the clinical aspect has always been kept in the foreground, and as much of the administration as possible has been delegated to clerical subordinates. That this has not been prejudicial to the work is witnessed by the confidence in it of successive High Commissioners, Ministers, and Under Secretaries, and by its popularity among all classes of Egyptians, even among those who are most opposed to the continuance of any British influence in the country. It is thoroughly recognised by these that they owe an admirable system of cure and prevention of conditions which weigh heavily on their country to a British benefactor primarily, and secondarily to a British surgical administrator. Over £100,000 have been raised for capital expenditure by private donations and by subsidies from county and municipal councils, and the Government grant for maintenance expenses amounts approximately to £50,000 a year. Provision has been made for carrying on ophthalmic clinics at all the provincial primary schools, as well as at several schools in Cairo and Alexandria, where particular attention is paid to the correction of errors of refraction. During the last year Mr. MacCallan was appointed Deputy Director-General in charge of all Medical Services, but he preferred to remain an ophthalmic surgeon, and has returned to practice in London.

FROM various sources information has been received of the recent increase of plague in the Punjab, and the figures in the last Monthly Epidemiological Report, issued by the Health Section of the League of Nations, confirms the bad news. In the figures given by the Director of Public Health for the Punjab, the total of cases was 328 for the week ending March 26th. There were 102 deaths reported from plague in Lahore. Plague cases have been reported throughout the beginning of the year from South-Eastern Russia and the Kirghiz and the Kirghiz Republic, including the Ural and Bukeiev Governments. The disease has been reported from Siberia, and cases have been identified in two European ports—namely the Piræus and Lisbon; but figures from other places, however much they may keep before us the lesson of watchfulness, become negligible when compared with the Indian statistics. In the first completed month of this year there were over 16,000 cases of plague in British India, and 75 per cent. of the cases were fatal. The figures show an ominous rise on those of the corresponding period of last year.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXVIII.—THE TREATMENT OF EARACHE.

OF all the causes of earache the one of outstanding importance both owing to its frequency and to the seriousness of its possible sequelæ is acute otitis media. Every case of earache should be approached as though this were the cause until it is proved not to be. Briefly, the treatment of acute otitis media consists in incision of the drum-head if necessary at the proper moment; the decision as to whether the condition is ripe for this small operation can only be made by examining the ear with the aid of the forehead mirror or the electric otoscope. Those medical men who are unaccustomed to the use of these instruments should refer any case of earache in his practice to some fellow practitioner who has had practice in the examining of drum-heads, or should call in a specialist. It is necessary so to educate opinion in the profession that the application of warm oil or glycerine for earache or the insertion of drops of hydrogen peroxide without examining the drum-head should be deprecated as strongly as, for example, the administration of castor oil to a child with the belly-ache without examining the iliac fossa to exclude appendicitis. A detailed description of the physical signs of the inflamed drum-head and of the treatment of this condition will be found elsewhere,[1] but stress may be laid upon certain important points.

1. *Warmth* best relieves the pain, but it should not be employed in the form of hot fomentations. These cause the skin to become sodden; the skin in the external auditory meatus swells and the epithelium peals off and may block the meatus. In this way the subsequent examination of the drum-head becomes impossible, so that the changes occurring therein cannot be observed. Thus a drum-head may be incised unnecessarily or a case may be allowed to go too far without paracentesis, so that the risk of mastoiditis is greatly increased. The best way to apply warmth is to make the patient lie with the bad ear upon a half-filled rubber hot-water bottle which is covered with flannel. In addition, it is well to cover the head with a flannel cap so that the ear is still protected if the patient roll over in the night.

2. *Removal of Wax.*—To remove wax from the ear of a small child or even of an adult who has pain in that ear is the most difficult operation in otology. If it cannot be done with ease and at once, it is best to make no further attempt but to give the patient an anæsthetic. The ear can then be cleaned up and the drum-head examined under anæsthesia. If this examination gives evidence of an acute otitis media the incision can be made at once. There is but little fear of giving an anæsthetic unnecessarily, for the association of pain in the ear with such tenderness that wax cannot be removed nearly always indicates acute otitis media.

3. *Anæsthetics.*—A few otologists acquire so high a skill that gas only is needed for them to incise the drum-head, but for the practitioner it is better to give an anæsthetic which gives more prolonged unconsciousness. This enables him to clean out the ear, to pick up the landmarks on the drum-head, and carefully to incise the most prominent part. I have not found any local anæsthetic which is efficient for the incision of an inflamed drum-head, though some say that it can be done after the application of Bonain's solution (equal parts of cocaine, menthol, and pure carbolic).

4. *The Adult Patient.*—The treatment is the same in the adult patient, though the pain may not be so severe, and the subacute type, which will resolve

---

[1] The Treatment of Acute Otitis Media in Children, British Journal of Children's Diseases, April–June, 1923.

without incision or rupture of the drum-head, may be more common than in the child; but the possible sequelæ either in the form of acute mastoiditis with its complications or in the form of chronic suppuration are just as likely to occur and to lead to as tragic a termination if the condition is neglected.

Inflammation of the Skin of the Meatus.

The examination of the ears, which the practitioner has made in order to exclude otitis media, will also have drawn his attention to the other common aural lesion of earache. This is some inflammation of the skin of the meatus especially in the form of a boil. The treatment depends first upon the decision as to whether the boil should be opened or not. The pain in this condition is so intense that any visible swelling may be incised, even if there is no pus therein, with considerable advantage owing to the relief of tension in the inflamed part. If the boil is pointing it is well to incise without waiting for it to burst; even if it has already burst it should still be incised unless the discharge is very free. In both these conditions the relief of tension will so ease the pain that the patient should not be allowed to go without this benefit. Here, again, I use a general anæsthetic, though it is said to be possible to do the small operation under Bonain's solution. After the boil is opened it should be emptied of pus and the interior touched with pure carbolic acid.

The Toilet of the Outer Ear.—Further treatment of such a case, and the whole treatment of a case which does not need incision, depends upon the toilet of the skin of the outer ear. This cannot be left to the patient, but must be carried out by the practitioner in a good light with a wool-carrier. The best cleansing agent is alcohol in the form of methylated or of rectified spirit or of scent. The whole of the skin of the meatus and of the neighbouring part of the pinna should be gently rubbed in such a way as to bring from the ear the superficial epithelium and any wax or secretion that may be obstructing the orifices of the various glands of the skin of the meatus. The whole area may be painted with tincture of iodine after it is thoroughly cleaned. It is best to repeat this treatment daily for a few days, but if this is impossible the patient may himself apply some ung. hyd. ox. flav. to the skin of the ear. Sometimes it is easier for him to apply this in the form of drops, which may be made by suspending two or three grains of the yellow oxide of mercury in an ounce of equal parts of glycerine and spirit. Here, again, fomentations should be avoided; they tend to make the meatus full of a nasty decomposing mess, and to spread the boils from the ear to the skin of the neighbouring parts. The chronic form of furunculosis is sometimes most intractable and tends to recur whenever the patient is out of sorts.

Pain Referred from the Mouth.

If the ear presents no obvious cause of the symptom the mouth should be examined. Most often a carious molar tooth is at fault, usually the back one, and more frequently the lower than the upper. Any form of acute inflammation in the region of the fauces will cause earache; it is not uncommon in cases of tonsillitis, parenchymatous or follicular, in other forms of acute pharyngitis, and after operations on the tonsils. In all these lesions the inflammation may spread up the Eustachian tubes to the middle ear and an acute otitis media may be the cause of the pain. Therefore, it still behoves the doctor to examine the drum-heads as soon as complaint is made of earache; he must not jump to the conclusion that the pain is referred. One form of subacute pharyngitis is that which attacks the naso-pharynx in adults and affects particularly the band of lymphoid tissue which runs down the lateral wall of the pharynx. The only thing to be seen through the mouth is an infection of the mucous membrane behind the posterior pillar of the fauces on either side. In such a case there may be quite intense earache occurring at the height of the excursion of the structures in the act of swallowing.

Pain or Tenderness Near the Ear.

Certain lesions cause a pain which the patient describes as earache but which proves on critical examination to be pain or tenderness near the ear. The commonest lesion here is an enlarged lymph gland, either over the mastoid, beneath the lobule of the ear, or immediately in front. Any of these may be enlarged from a small cutaneous lesion in the meatus insufficient in itself to cause pain. The mastoid gland again may become enlarged from the bite of the head louse. It needs sometimes the very closest examination to distinguish between a nit and a particle of dandruff sticking to a hair. Another lesion which may cause this gland to be enlarged in a woman is a scratch in the scalp from a hairpin or a hatpin. Pain near the ear may also be caused by a lesion of the temporo-mandibular joint or of the parotid.

Earache Without Apparent Lesion.

When all these regions have been examined there remain a few cases of earache in which no lesion is immediately apparent. Sometimes a minute piece of hard wax, perhaps no larger than a pin's head, sticking on the drum-head may cause the symptom. Cases have been known in which persistent earache has been relieved by paracentesis, although no change could be seen in the drum-head, and no tension was apparent when the incision was made. But before this operation is performed the mouth must again be examined. An unerupted and impacted lower wisdom tooth pressing against the molar in front of it may cause earache; this will be discovered or excluded by means of the X ray. In the adolescent an erupting lower molar may have the same effect. Lastly, it is possible that the mere distension of a crypt or crypts or the supra-tonsillar fossa of the tonsil by one or more of those ovoid soft concretions that can so often be expelled therefrom may be a cause of earache. If such a thing were suspected the treatment would be to empty the cavity if necessary after slitting up its orifice.

T. B. LAYTON, M.B., B.S. Lond., F.R.C.S. Eng.,
Surgeon in Charge, Throat and Ear Department,
Guy's Hospital and St. George's Dispensary.

Corrigendum.—In Dr. J. B. Mennell's article on the Treatment of Sprains, which appeared last week under this heading, the sentence p. 816, col. 2, line 51, should read: "When swelling has disappeared *from the front of the elbow* restoration of movement," &c.

OPHTHALMIC HOSPITAL OF THE ORDER OF ST. JOHN, JERUSALEM.—The report of this hospital for 1923 records the great increase in the amount of work accomplished since the war—14,777 new cases as compared with an annual pre-war average of 9849—an increase made possible by extension of the buildings and an increase in the subordinate personnel. The number of operations, most of them (62 per cent.) for trichiasis, has increased from 1926 to 4169, while the number of surgeons employed is only two, so that in the opinion of the warden the limit has been reached in this direction until a third surgeon is appointed. The need is pressing. During the past year approximately one-half only of the cases requiring operation could be admitted or operated on as out-patients. The remainder had to return to their villages unrelieved and disappointed.

ROYAL WEST SUSSEX HOSPITAL.—The annual report of this institution for the year which ended on Dec. 31st, 1923, is a document more satisfactory than others of recent years, for the statement of accounts shows a small balance in hand, while the expenditure shows an appreciable decrease and the income has been fairly maintained. The income for 1923 was £9816, and the expenditure £9752. The report for 1922 showed a cash deficit of £564. The in-patients treated during the year numbered 978 and the out-patients, who made 6713 attendances, numbered 1761. In addition, 1020 attendances were made in the X ray department, and 2509 in the electrical massage department. It is of interest to note that the board of the hospital keeps in close touch with the work of other hospitals by the attendance of its representatives at the meetings of the Regional Committee for Hants, Dorset, and West Sussex at different hospitals.

Special Articles.

BRITISH EMPIRE EXHIBITION, WEMBLEY.

TROPICAL HEALTH SECTION.

It may not be generally known that in the Hygiene Section of the British Empire Exhibition as many as 27 different diseases are the subject of special educational propaganda. The section is housed in the Government pavilion and occupies one of the best positions in the exhibition. A small book, descriptive of this section, has been published with a view to bringing home to the public the great advances made in this field and to emphasise the imperial significance of tropical diseases.

The Tropical Health Committee.—With Sir Humphry Rolleston as chairman and Sir W. B. Leishman as deputy chairman, this Committee is composed as follows: Major E. E. Austen, Dr. Andrew Balfour, Sir P. W. Bassett-Smith, Dr. J. E. Butler, Sir R. Havelock Charles, Dr. J. B. Christopherson, Lieut.-Col. W. W. Clemesha, Dr. S. H. Daukes, Mr. G. C. Dudgeon, Dr. N. Bishop Harman, Mr. Guy A. K. Marshall, D.Sc., Dr. H. B. G. Newham, Prof. R. Newstead, F.R.S., Capt. J. Ramsbottom, Surg.-Commander T. B. Shaw, Dr. H. S. Stannus, and Prof. J. W. W. Stephens. Illustrations and specimens have been provided by individual contributors and by the Natural History Section of the British Museum, by the Liverpool School of Tropical Medicine, the Royal Army Medical College, the Royal Naval College, the Wellcome Bureau of Scientific Research, and the Imperial Bureau of Emtomology and Mycology.

Guiding Principles of the Exhibition.

The Tropical Health Section is intended to give a bird's-eye view of the various diseases dealt with—how they are caused and prevented. It is essentially an exhibition for the layman, but no attempt has been made to soften the picture which is presented in all its naked truth for the benefit of the administrative layman who has to deal with the problems arising from these diseases. The Tropical Health Section is in four parts. There is a jungle scene devised to emphasise the material benefits to be derived from well-regulated preventive measures, and the differences between 50 years ago and to-day are contrasted in two well-planned tableaux. The second part, or Disease Section, deals with 27 diseases, and one portion is devoted exclusively to that large group, the diseases in which are spread by biting insects. Each disease is briefly described with the help of pictures, photographs, models, and specimens, and there is a short introductory account of its history and the means at present available for fighting it. There are also specimens and models of the insects which play a part in disseminating these diseases. This portion includes such diseases as malaria and yellow fever. Another group of diseases are those essentially due to intestinal infections, such as typhoid fever. Food-deficiency diseases are represented by scurvy and beri-beri, and considerable space is devoted to skin diseases, yaws, and leprosy. In the third section, devoted to hygiene, a uniform illuminated device is employed to provide statistical information at a glance. The fourth section deals with plant diseases.

Tropical Diseases.

Sleeping Sickness, Malaria, Blackwater and Yellow Fever.—Special attention is called to photographs of natives suffering from sleeping sickness, the characteristic somnolence, emaciation, and puffiness of the face being well shown. Wax models and specimens of the tsetse-fly and its developmental stages, and photographs depicting its haunts and breeding-grounds are shown. It is pointed out that a well-organised campaign against the tsetse-fly may practically stamp out the disease, as has been proved in the Island of Principe. The malaria exhibit is remarkably complete; a central exhibit shows by means of models and actual specimens the stages and processes of breeding, and there are models of the parasite in the human and mosquito stages. There are several illuminated devices demonstrating the value of preventive measures. The relation of blackwater fever to malaria is briefly discussed, and a short account is given of the genesis and course of yellow fever. A model is shown of the "tiger mosquito" responsible for this disease, and an interesting account is given of how small fish may be employed to eat the larvæ in the breeding places of this mosquito. A pictorial account is given of the recent successful campaign in Guayaquil against this mosquito.

Dengue Fever, Filariasis, Guinea-worm Disease, and Relapsing Fever.—The relation of dengue fever to mosquitoes is pointed out, and in the exhibit devoted to filariasis there is a specimen of elephantiasis of the leg showing the gross deformity resulting from this disease. There is also a wax model of "Calabar swelling" caused by the West African "loa loa" worm. The life-history of the guinea-worm is also pictorially described, and there is a model of the ulcer produced by the female worm. There are also specimens of the water flea in which the embryos of this worm develop. The various spirochætes responsible for relapsing fever, syphilis, and other diseases are demonstrated, and their mode of propagation explained.

Plague, Sandfly Fever, Rocky Mountain Fever, Oriental Sore, and Trachoma.—There are photographs and paintings of plague patients and pathological specimens illustrating three varieties of this disease. There is much in this exhibit of historical interest, and the leaden crosses, which were buried with plague corpses, are shown. The costume worn by physicians attending plague patients, and certain instruments for opening the buboes, are included among the exhibits, which also show ancient pictures of incidents connected with plague. There are original paintings showing the development of the sand-fly, and this particular exhibit gives a good idea of the detailed work required to investigate a disease caused by an insect hardly large enough to be visible to the naked eye. The exhibits of Rocky Mountain fever and "Oriental sore" are an eloquent tribute to the efficiency of research, and it is pointed out how recent advances in treatment as well as prevention have made the outlook for these diseases much more hopeful. There are excellent paintings emphasising the seriousness of trachoma, and justifying the elaborate efforts made to keep this disease out of the British Isles by the Alien Acts.

Dysentery, Typhoid and Paratyphoid Fevers, Cholera, Hookworm Disease, and Bilharziasis.—There are some excellent pathological specimens showing liver abscess following amœbic dysentery, and special attention is directed to the decline in the typhoid and paratyphoid fevers by an illuminated statistical device contrasting the incidence of these diseases in the South African campaign and the late war. An exhibit of the method of preparing vaccines shows the meticulous care taken to guarantee purity and accuracy of dosage. In connexion with the typhoid group of fevers there are sundry exhibits drawing attention to the possible dangers of eating shell-fish "fattened" in polluted water, and of eating uncooked vegetables, such as watercress, contaminated by sewage. With reference to the mortality from cholera, it is interesting to note the illuminated statistical device showing the efficiency of intravenous injections of saline solution as advocated by Sir Leonard Rogers. There are also paintings illustrating the causation of cholera. The methods by which the hookworm attaches itself to the intestines are illustrated, and there are large wax models of the heads of the two species of hookworm which give most trouble. The exhibit of bilharziasis stresses the value of preventive measures; this disease has recently been located in Portugal.

Scurvy, Beri-beri, Pellagra, and Tropical Skin Diseases, including Leprosy.—The relation of scurvy to diet is driven home by an exhibition of samples or models of various anti-scorbutic foodstuffs. There is a specimen of a dilated heart from a case of severe beri-beri to teach the lesson that acute heart failure is one of the chief dangers of this disease. A sample of the diet consumed by a ship's crew suffering from beri-beri is shown. The existence of pellagra in our midst is drawn attention to by paintings of patients observed in English asylums. Various rare skin diseases in the tropics are demonstrated by photographs, and the problem of leprosy is dealt with by paintings, photographs, and illuminated statistics showing the effects of preventive measures.

Sunstroke.—There are various exhibits showing the means best suited to the protection of the head and spine by helmets, spine pads, and other contrivances, and there is a small model of a double-roofed tent. There is also a rough model of the improvised bath-house used in emergencies with success for the treatment of heatstroke in Mesopotamia.

Model of a Tea Garden.

The central exhibit contains a model of a manager's bungalow built in two storeys, the upper being carefully screened with mosquito gauze, and containing five rooms in the form of a cross which gives the maximum amount of outside wall, and catches every breath of wind. A house of this kind should be healthy in almost any country, however malarious. The latrines are connected with the main block by a masonry path devised to prevent hookworm disease. The banks of the stream which runs through the garden are riveted with brick to prevent mosquito breeding, and there is an arrangement for oil to drip into the water to render it less attractive to the mosquito.

Pilgrimages, Marine Quarantine, Vaccination, Oriental Sanitary Appliances, and Chlorination of Water.

Pictures are shown illustrating the sanitary problems associated with pilgrimages and festivals, and useful hints are given as to the sanitary arrangements necessary for such a situation. In the Marine Quarantine exhibit there are shown models of port health officers' boats especially prepared for isolating a patient with yellow fever from the local mosquitoes. The method of preparing vaccine lymph from calves is demonstrated, and it is shown how much more troublesome this process is in hot than in cold countries. Dr. Allan Green's apparatus for purifying calf lymph with chloroform is also demonstrated. The sanitary fittings usually found in European houses not being always to the likings of the conservative Oriental, English manufacturers have designed special fittings to closets, urinals, &c., for the needs of India, China, and the Far East; these fittings are said to be much superior from a sanitary point of view to anything which can be manufactured in the countries for which they are intended. Apparatus for the chlorination of water is also displayed.

The keynote of the Tropical Health Section is hopeful realism; its realism must be almost painful to some laymen, but there can be no doubt as to the hopefulness of the outlook, of the prospect that in the near future many of the Empire's territories will cease to deserve the title "The White Man's Grave."

NEW CORONER FOR SOUTH LONDON.—To fill the vacancy caused by the death of Mr. G. P. Wyatt, the London County Council has appointed Surgeon-Commander A. D. Cowburn, M.R.C.S., D.P.H., L.R.C.P., Barrister-at Law, to be coroner for the Southern District of the County of London. The inclusive salary attaching to the office is £981 18*s*. per annum, but it is probable that the Duchy of Lancaster will appoint Commander Cowburn to the vacant franchise district of Clapham at a salary of £59 8*s*. a year, making the combined salary £1041 6*s*. a year. A condition of the appointment is that the occupant shall "devote his whole time to the duties of his office, not practise any profession or hold any other public appointment, and resign on attaining the age of 70 years."

THE TUBERCULOSIS SOCIETY:
MEETING AT CAMBRIDGE.

(*Concluded from p. 818.*)[1]

FOLLOWING the papers reported in our last issue which were read at the Cambridge meeting of this Society, Dr. A. Stanley Griffith gave a communication on

Lupus.

Dr. Griffith's paper dealt with atypical tubercle bacilli in natural tuberculosis with special reference to those occurring in lupus. Since Cobbett first isolated an atypical strain of tubercle bacillus from a case of lupus, the bacteriology of lupus has been investigated by Dr. Griffith. Dr. Griffith's work was carried out in the Field Laboratories, Milton, and he paid a tribute to Sir G. Sims Woodhead's encouraging support. In the first series of 20 cases of lupus there were only three strains conforming to definite types, the remainder did not conform exactly either to the human or to the bovine type as far as their virulence to experimental animals was concerned. Culturally, the strains could be classified as bovine or human. The main objects of subsequent investigations were (1) to search for atypical strains in other varieties of human and animal tuberculosis, (2) to seek direct evidence of modification of strains in skin lesions, and (3) to ascertain if, by examining a large number of cases of lupus, the finding of the high proportion of atypical strains in the first series could be confirmed. The observations of Dr. A. Eastwood and Dr. F. Griffith between 1911 and 1916 were incorporated with those of Dr. A. S. Griffith. In the human subject atypical strains were found at first only in lupus, but in the later investigations atypical strains were obtained also from other varieties of human tuberculosis. Strains with modified virulence resembling those from lupus were, however, very uncommon and occurred only in about 0·6 per cent. of the cases. The avian tubercle bacillus was not found in the human being. In animals atypical tubercle bacilli were not of frequent occurrence. Of 132 cases of tuberculosis in the pig, 94 were due to the bovine type, 31 to the avian, four to the human type, and in three cases the infection was due to more than one type of tubercle bacillus; only three of the porcine strains were atypical. In the six cases in which tuberculosis in the horse was investigated, the type was invariably bovine, although in three of these cases the characters of the bacilli were not in every respect strictly those of the bovine type.

Up to date 140 cases of lupus have been investigated, the tubercle bacilli being classified according to their behaviour on culture and their virulence to rabbits, guinea-pigs, and certain other experimental animals. Two main groups, each with a subgroup, were distinguished. Of the 71 cases showing typical bovine characteristics on culture, 22 were characteristically virulent to all the species of experimental animals tested. Of the 66 cases showing typical human characteristics on culture, 19 showed standard virulence to experimental animals. There were also three cases in which the strains were atypical in cultural characteristics. It was noticed that there were no clinical features distinguishing cases of lupus according as the infection was of the bovine or human type. With regard to the question, "Do the atypical lupus tubercle bacilli acquire their special characteristics during residence in the cutaneous tissues?" Dr. Griffith stated that all the evidence goes to show that lupus is produced originally by tubercle bacilli of normal virulence, and that their virulence becomes modified in the course of the disease. The evidence in support of this view is direct and indirect. With regard to the former, re-examinations were made of 24 cases of lupus, the characters of the strains in one and the same case being compared on different occasions. In 6 of these 24 cases the first strains were fully virulent bovine tubercle bacilli, and in each instance the second, or a later, strain was definitely less virulent than the first, though the tubercle bacilli were unaltered in cultural characteristics. As to the suggestion that daylight may attenuate the virulence of tubercle bacilli in the cutaneous lesions of lupus, Dr. Griffith had been unable to find uniform differences in the virulence of tubercle bacilli obtained from lupus areas exposed to, or concealed from, daylight. In one case a fully virulent bovine strain was obtained from lupus of the face of 33 years' duration.

---

[1] In the report last week of Dr. Matson's remarks on American tuberculosis work the death-rate in 1910 of 202 and in 1922 of 94·2 should, of course, have been given as *per 100,000*.

Lupus being common in the exposed parts of the skin, it was thought that the subnormal temperature of the skin of these parts might affect virulence, but passage experiments through toads did not support this hypothesis, though the duration of residence of tubercle bacilli in toad tissues was as long as seven years. No decrease in virulence or change of cultural properties being observed, support was not given to the view that mammalian tubercle bacilli could be easily modified in the tissues of cold-blooded animals. Dr. Griffith had noticed that although tubercle bacilli had lost their virulence to the experimental animal, there was no loss, but rather an increase, of their virulence to the individual suffering from lupus. Hence the conclusion that the changes observed in the pathogenic properties of tubercle bacilli during residence in lupus lesions are not degenerative, but the result of adaptation of the bacilli to conditions in the skin, different from those which obtain in other organs, of the nature of which we have no definite knowledge.

Other points in the paper were that passage of atypical tubercle bacilli through the guinea-pig did not influence their virulence, and that from the same patient different strains might be obtained, the virulence of which was not identical. He had also noticed that cultural qualities were more stable in the human body than the degree of virulence to the experimental animal. In addition to his communication on lupus, Dr. Griffith gave much information about the character of the infecting organism in the cervical gland and other varieties of tuberculosis of man, and he showed how the incidence of bovine infection declined as the age of the children examined increased. In the discussion which followed, Dr. S. Roodhouse Gloyne dwelt on the apparent waywardness and variability of guinea-pigs which are not obliging enough to behave with the frigid uniformity of the standardised test-tube. He also observed that giant cells seemed to be more common in tubercles provoked by the human type than in those due to infection with the bovine type.

Mr. G. R. Girdlestone read a paper on

The Present-day Treatment of Bone and Joint Tuberculosis.

His paper, in which he outlined general principles and considerations, but gave no statistical account of his own work and of the results achieved, laid special emphasis on the importance of allowing plenty of time for the treatment of surgical tuberculosis. He confessed that the believer in the short cut to health was anathema to him, and though he admitted that heliotherapy might be beneficial, he did not confess to that frantic enthusiasm exhibited by the devotees of this cult. Certainly, the child who pigmented well under the sun was likely to do better than the child whose skin did not pigment easily, but it was a far cry from this observation to the deduction that pigmentation itself was the main beneficial factor. In this connexion he pointed out that between the old days of white children and these days of brown children, there was a decade or so when rosy-cheeked children thrived in open air wards. The rosy-cheeked child seemed no longer to be fashionable in institutions for surgical tuberculosis, although of the vigorous health of this breed Mr. Girdlestone was convinced. As long as the disease was acute, he was sure that immobilisation was essential. With regard to the value of Albee's and similar operations, he was not in favour of them for the child, for whom time is not such a vital factor as it is for the adult. Again, a child's bone-graft is apt to be too weak and elastic to immobilise the spine effectively. He was, however, in favour of bone-grafting operations in certain adult cases of Pott's disease. He had found ultra-violet light most beneficial when tuberculous lesions were superficial. Bier's treatment by passive congestion did not impress him, and he observed that Rollier prefers to keep the diseased limb tilted up.

Mr. A. Cook, of Addenbrooke's Hospital, gave an account of a visit to the Finsen Institute in Copenhagen, where he had studied the treatment of surgical tuberculosis with universal carbon arc light, the clothing of the patients being limited to spectacles. He mentioned a case of Pott's disease, illustrating the difficulties a young surgeon may encounter when an eminent consultant reverses the correct diagnosis. The patient had been treated for Pott's disease by immobilisation for two years, at the end of which the eminent consultant appeared on the scene and diagnosed "hysterical spine," for which diagnosis the patient had to pay some time later with a tuberculous knee, which the most eminent of consultants could hardly have regarded as hysterical.

Visit to Papworth Colony.

The meeting of the Tuberculosis Society ended on April 12th with a tour of inspection of the Papworth Colony, where Dr. P. C. Varrier-Jones answered many scores of questions fired at him by visitors, most of whom possessed expert knowledge of the administration of institutions for the tuberculous. The success with which he came through this ordeal was certainly a tribute to himself and, perhaps, to the soundness of the scheme to which he has devoted unceasing energy for many years.

MEDICAL WOMEN'S FEDERATION.

MEETING OF COUNCIL.

A meeting of the Council of the Federation was held at the London School of Medicine for Women, 8, Hunter-street, London, on April 12th, Lady Barrett, President of the Federation, being in the chair. Among the various matters considered the following were of special interest.

The plan of action of the Medical Women's Federation with regard to equal pay for men and women in the profession for all posts was brought up for reconsideration. It was pointed out that an increasing number of public authorities were attempting to obtain medical women at a lower salary than medical men, and were offering them £500 for posts where the British Medical Association minimum salary would be £600. Many instances were reported where women candidates had refused to take such a post, owing to the representations of the Medical Women's Federation, the British Medical Association, and the Society of Medical Officers of Health, and in one case, at any rate, the salary had in consequence been raised to £600 and the woman appointed. It was considered, however, that under the present circumstances it will be a work of great difficulty to prevent women accepting posts below the British Medical Association minimum, and success can only be looked for if the support of the men in the profession is given. It was felt strongly that the subject concerned the profession as a whole, a point of view which the British Medical Association has always maintained. To accept the principle of lower pay for women than for men, for equal work, would mean not only the introduction of competition between the sexes on very undesirable lines, but would almost certainly lead in the long run to the lowering of salaries for men also. In conclusion, a resolution was proposed and passed unanimously that:—

"The Medical Women's Federation reiterates its firm conviction of the absolute necessity for maintaining the principle of equal pay for equal work as between men and women."

Reports were received and discussed from the various subcommittees of the Federation and from its representatives on the British Medical Association committees and other bodies. The report of the Venereal Diseases Subcommittee brought forward evidence of extremely unsatisfactory conditions permitted in some of our Chinese colonies, and the following resolution, to be sent in to the Secretary of State for the Colonies, was moved and carried:—

> "The Medical Women's Federation calls upon the Government to bring the Crown Colonies into line with the British law in regard to the penalties for brothels and disorderly houses, and, particularly in the case of Hong-Kong and the Straits Settlements, to break up and abolish all existing vice areas or streets where brothel-keeping is at present allowed."

Miss Mabel Ramsay, the Federation's representative on the British Medical Association Insurance Acts Committee, reported the very satisfactory work that had been accomplished by that Committee, and proposed that a vote of thanks should be sent by the Federation to the chairman, Dr. H. B. Brackenbury, and the officers of the British Medical Association for the care and skill taken in presenting the case for the panel doctors to the recently held Council of Inquiry. This was passed unanimously. Five members were elected to represent the Federation on the Council of the Medical Women's International Association—Lady Barrett, Dr. Christine Murrell, Dr. Jane Walker, Dr. Dickinson Berry, and Miss Louisa Martindale. The meeting of the International Association will take place on July 15th, 16th, and 17th at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W.

The Council received with deep regret notice of the death of two of its members, Dr. Ann E. Clark and Miss Ethelberta Claremont.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Asylum Strike in Donegal.

THE difficulties in the Tirconaill Mental Hospital, Letterkenny, produced by the strike of attendants, appear not to have been completely surmounted. Reports a few days ago stated that the situation was normal, the committee having been able to secure the services of a number of demobilised soldiers to act as attendants on the male side. But there have since been accounts of retaliation on the old staff by the new female attendants. One can hardly suppose, in any case, that a staff of trained attendants can be replaced in a moment by a band of untrained persons without grave loss of efficiency. It is to be hoped that the Government will order an inquiry into the events which led up to the strike. On the face of it the committee seems to have acted in an imprudent, or even provocative, manner. Since 1920 there has been in force an agreed rate of remuneration to the attendants in all the asylums in Ireland. This rate was settled at a conference between representatives of the committees and of the attendants in all the asylums. Recently, the committee of the Tirconaill Mental Hospital at Letterkenny notified the staff of its intention to make a cut of 10 per cent. on the current wage. The order was peremptory and made without any conference with other asylum authorities or with the attendants. At the same moment a vacancy occurred for a head attendant, and the committee made it a condition of appointment that the head attendant should not be a member of the attendants' union. This stipulation, even more than the cut in wages, appears to have irritated the attendants.

The Apothecaries' Hall.

The Apothecaries' Hall has given notice of its intention to apply to the Oireachtas in the present year for permission to bring in a Bill, the main object of which is to alter the title of its licentiates. At present the licentiate is styled simply "Licentiate of the Apothecaries' Hall, Dublin," and the Hall wish in future to use the description, "Licentiate in Medicine and Surgery of the Apothecaries' Hall, Dublin." No doubt such a change would, in itself, be an advantage both to the licentiates and to the public, since the present title fails to make it clear that the licentiate is qualified to practise medicine and surgery. A change of this sort would be useless, however, unless the new title were registrable with the General Council of Medical Registration and Education. The Hall, therefore, asks in its Bill that the registrar of the branch council should be empowered to register the proposed title as a qualification to practise medicine and surgery. If the Bill is proceeded with, it will raise in a difficult form the question of the relation of the Oireachtas to the Medical Register.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Essential Property of Homologous Milk.

ON March 28th last Prof. H. Finkelstein, of Berlin University, addressed the Medical Society of Johns Hopkins Hospital on the Inferiority of Cows' Milk Feeding in Human Beings. Referring to the so-called "modified" or "humanised" milk, he said that he knew of nothing more liable to produce acute diarrhœa in human infants. Since the resulting diarrhœa is acid the cause must be fermentation not of proteins, as many theorists had claimed, but either of fats or of sugars. Prof. Finkelstein regarded the problem as a race between absorption and fermentation, the infant suffering from heterologous milks because of the delay in their absorption. That this delay actually is constant with heterologous milks he has himself shown by plotting the blood-sugar curve for infants after ingestion severally of human and of cows' milk. The curves reproduced at this lecture showed that the heterologous milk was absorbed much more slowly and less completely than the homologous, so that absorption of lactose from cows' milk was completed an hour and a half to two hours after the human milk lactose would have been completely absorbed. He was not able to point to the specific substance in heterologous milk which causes this delay, or to any specific material in homologous milk which stimulates absorption. Cows' whey was found to be delayed in its absorption equally with milk. However, if the albumin is removed from this whey, or if the whey is dialysed, the sugar in the resulting fluid is absorbed as rapidly as that in homologous milk. Dr. Finkelstein suggested that not only is the delayed absorption of cows' milk responsible for acute diarrhœa, but also that many of the chronic dystrophies may be charged to a condition of acidosis resulting from incomplete metabolism, also due to the inadequate supply of sugar to the blood-stream. Thus is opened up to the biochemist a field of investigation full of promise.

Nursing Standards.

The movement to establish the full professional status of nursing in this country gains impetus month by month. The new Yale School of Nursing has issued a prospectus for the coming academic year—the first of its existence. It will be remembered that this school is largely due to the generosity of the Rockefeller Foundation and that its aim is primarily to secure efficient nurses for the more important posts in public health work, bearing in mind the rapidly increasing demand for such workers to keep pace with the swift evolution of public health work throughout the States. At Yale the professional training of the student in the actual care of the sick will be strengthened by a knowledge of the underlying theory in regard to disease as well as the social, psychological, and hygienic aspects of the case. Specialised training is offered in medicine, surgery, obstetrics, and pædiatrics. Full information can be had from the Dean.[1]

A somewhat similar, but in some respects more extensive, scheme has been organised in the Middle West in connexion with Antioch College. The latter institution, though founded by Horace Mann in the middle of the last century, has during the past two or three years been reorganised on an original plan which is creating much interest among American educationists. With the object of developing an all-round character, rather than to pay their way through college, the students spend each alternate five weeks of their college life employed in the factories and businesses of the near-by cities. This is not the place to discuss the merits or demerits of this kind of education,[2] but the development of a nursing school out of this general scheme is distinctly of interest. The course lasts typically for six years. The candidates receive as much theoretical training at the Miami Valley Hospital as nurse probationers normally receive. In addition, during alternate five-week periods they are taking the course for the B.S. degree only slightly modified to give emphasis to their especial interests. At the end of five years they receive their nurse's diploma. It is intended that the last year in college shall be spent in completing the science course and in obtaining practical experience in public health or industrial nursing. The geographical position of Antioch College and its close association with the large industries of the Middle West give it exceptional opportunities to find this kind of experience for senior students. The fact that during their five weeks in college the students are some 20 miles distant from the hospital wards must add a spice of variety to the training.

VIENNA.

(From our own Correspondent.)

Treatment of Climacteric Condition by the Action of X Rays on the Hypophysis.

In the Vienna clinics experiments are being conducted with a view to alleviating the worrying conditions of the climacterium by applying X rays to the hypophysis. At a recent meeting of the Medical Society Dr. Borak reported on the results obtained by this method in 25 women treated in the X ray department of Prof. Holzknecht. The patients had either been operated on for abdominal conditions or had been previously treated by X rays for myoma or dysmenorrhœic complaints. When climacteric conditions supervened, Dr. Borak applied small doses of X rays to the hypophysis. The effect was most gratifying. Headaches and vertigo disappeared, congestions were much less frequent, and the sleep improved. In one case only was the method unsuccessful, and the patient received hereafter an application over the thyroid which proved efficacious. The correlation between ovary and hypophysis, as well as between thyroid and hypophysis, is well known. The rationale of X ray applications to the hypophysis was based on the resemblance of climacteric conditions to vasomotor hypersensitiveness due to endocrine disturbance. The rays pass through the brain substance, which is not sensitive to them. In order to exclude suggestion, in some cases a lead filter was interposed so as to exclude all rays without the patient knowing it. No effect was noticed in such instances, but it appeared immediately when the filter was removed. Dr. Pohler, from the II. Gynæcological Clinic, reported on 165 patients subjected to the same method of treatment. He treated 54 cases of amenorrhœa, 52 of dysmenorrhœa, 51 with climacteric complaints, and 8 with dystrophia adiposo-genitalis. The last-named group showed no effect at all, but 50 to 80 per cent. of all the other cases had a marked improvement. All cases received repeatedly small doses only. The effect seems to persist for some months and is regarded by Holzknecht rather as the stimulation of a hypo-functionating gland than as the depression of a hyper-function. The addition of lime to the diet of these patients is also beneficial.

Statistics of Deaths due to Poison.

Quite a number of criminal attempts at poisoning have recently turned the attention of the public to the importance of poisonous substances obtainable without much difficulty by any would-be murderer. The records of accidental poisoning—chiefly in factories and workshops—also show that many people are handling poisons daily without due precautions. A report by the Board of Health of Vienna on the autopsies of the last 40 years conducted for forensic purposes—i.e., where death was due to external violence—states that out of 9664 such autopsies nearly 10 per cent. (948) were necessitated by poison. These deaths include 296 cases caused by gas; 144 by mineral acids and alkalies; 20 by mercuric chloride; 104 by phosphorus—no doubt taken as an abortifacient; 27 by arsenic; of these last-named only two cases were criminal. Forty-four deaths were due to poisonous mushrooms; 55 to veronal; carbolic acid killed 48 persons, whilst 46 succumbed to morphia, opium, or codeine; amongst these, two infants under 12 months, poisoned accidentally by an overdose of codeine. Prussic acid or potassium cyanide was the cause of death in 39 cases, potassium chlorate in 6, strychnine in 5, methyl alcohol in 9, whilst benzene and gasoline proved fatal in 5 instances and carbonic acid (CO_2) and CO in 26. It is interesting to note how few cases of criminal poisoning really prove fatal; arsenic in particular is "not reliable," whilst lead carbonate is slightly more popular with murderers. The chief source of danger of poisons is the neglect of precautions by factory workers. With the improvement of the system of industrial inspection, as stipulated by the new Factory Inspection Act, a large percentage of these accidental cases will be done away with, and the prohibition of the use of white phosphorus, which has now been in force for a few years here, has also had a most welcome effect. But of late cocaine hydrochloride has become a very potent source of danger. The cocaine habit has caught hold of so many of our weakened, morally unstable citizens that the police have had to take a firm stand against sellers of the drug to stop the traffic in restaurants and public-houses. Several fatalities have already been reported as a consequence of this habit.

Municipal Welfare Centres for Pregnant Women.

The Municipal Board of Health has organised an interesting system of maternity welfare centres, which has been in efficient working order now for some time. Out of the total of approximately 30,000 parturient women per year, 10,000 belong to the so-called better classes, 15,000 are members of one or another Krankenkasse, and the remaining 5000 have no corporation or wealthier friends to look after them. It is to these 5000 women that the municipal board turns its attention. In order to induce prospective mothers to apply to them the maternity centres offer a weekly grant of 50,000 kronen, together with free advice, treatment of the newborn, and free milk—all for a period of at least four weeks. The conditions are that the woman does not belong to a Krankenkasse, that she is poor, and that she submits, within the first four months of her pregnancy, to a Wassermann test. By this means the Board tries to find out all cases of syphilitic mothers and to subject them to a vigorous specific treatment. Statistics show that among 1700 syphilitic females who received no treatment during their pregnancy, 34 per cent. had a stillborn child or an abortion, 56 per cent. were delivered of a living child, which did not survive longer than five years, and the offspring of the remaining 10 per cent. lived longer, but were not healthy—they filled the hospitals and criminal asylums or were cripples. The years of war have resulted in a widespread infection of the lower classes, and the advantage of having yearly 5000 of the future mothers under control is obvious. Fifteen such maternity centres have been opened in Vienna, and have taken up their work. No doubt, in a short time the Krankenkasse will have to follow the example set by the city authorities.

Unveiling of a Commemorative Tablet to Zuckerkandl.

A short time ago an "In Memoriam" tablet to Prof. Zuckerkandl, the famous teacher of anatomy, was unveiled in the University hall of Vienna in the presence of a large gathering of former pupils and friends of the deceased. To illustrate the importance of this man's work, I may say that the astonishing development of modern rhinology is based principally on his researches into the anatomical conditions of the nasal structures and the accessory sinuses. A splendid collection of dry and wet specimens formed the foundation of his publications and is the pride of the Vienna Anatomical Institute. In addition, he was an excellent teacher, always prepared to keep the attention of his pupils by interesting comparisons with pathology, and, moreover, he was a keen artist, who imbued all who came in touch with him with the sense of beauty, even in the most unexpected objects. Prof. Tandler, pupil and successor of the celebrated teacher, handed over the tablet to the authorities of the University.

Summer Post-Graduate Courses.

The fees for University studies have been increased for the coming term to such an extent that they form a heavy burden to the poorer classes of students. Also the fees for matriculation for the degree of M.D. and for the doctor's diploma have been raised, the latter now costing 650,000 kronen, or £2. The classes for post-graduate work have become more expensive in proportion, especially for foreign students, but still they are below the pre-war rates if the gold value is taken as a standard. Yet the attractions of the numerous excellent post-graduate classes are so great that students flock from all corners of the world; the classes in July, August, September have already enrolled almost their full complement.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

"Loans of Honour" to Students.

LARGE numbers of students have been compelled to give up their studies owing to the rise in the cost of living, for although bursaries are provided by the various faculties, these cover the fees only, and the student must find for himself the money to meet the expenses of lodgings, food, and clothing during the years of his academic life. To render help in this necessary outlay the State has instituted, by a decree recently voted by the Chamber of Deputies, a system of "loans of honour." A student who requires aid may submit his request for a loan to a commission consisting of representatives of both professors and students, on the understanding that the money shall be refunded by him after graduation as soon as his means permit.

Franco-Anglo-American League against Cancer.

A general meeting of this League was held on April 8th, at which Senator Paul Strauss presided. The League was founded during the war with the object of attacking by every means the problem of the dread disease, and is a fine example of what can be done by international coöperation, not for the destruction but for the amelioration of human life. This year the League has established branches in Greece and in Spain, and year by year its work, scope, and material resources are becoming more and more important. It is only by united effort, financial as well as scientific, that the sinews of this war can be strengthened, and on April 12th the League held a remarkably fine exhibition of all the works of the painter Degas. This exhibition, which was inaugurated by the Queen of Roumania, realised a large sum of money; a programme signed by the Queen was sold for 1500 francs, and a flower which she had worn brought 500 francs.

Reception of Scottish Medical Students.

The annual visit of some 50 medical students of both sexes from Edinburgh University, who have come to take the course of instruction in our obstetrical clinics, began on Sunday, April 6th, when the Scottish students were met at the Gare St. Lazare by a delegation of their Parisian comrades and representatives of the Section of Medicine of the Association Générale des Étudiants. As in former years, the Association undertook the organisation of the visit. Prof. and Mme. Brindeau greeted our new guests, and after a cordial welcome and enthusiastic hurrahs several charabancs took the visitors to the Students' Union for supper, at which Mr. Gannat, in the name of the Section of Medicine, proposed the toast of "The Scottish Students," to which Mr. J. B. Colquhoun replied. On Monday, at 9 o'clock, a formal reception was held by the Dean, assisted by Profs. Brindeau, Couvelaire, and Jeannin, and the Dean expressed the honour which was felt by the Medical Faculty of Paris in welcoming the guests. Afterwards the students were allotted to the clinics of La Pitié, Baudelocque, and Tarnier. The Section of Medicine received the professors and the Scottish students on Thursday, April 10th, on the occasion of a soirée artistique.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: W. T. Haydon to the *Ajax* (on becoming ship of Senior Officer, Reserve Fleet, the Nore); P. T. Nicholls to the *Centurion*, as Squadron Medical Officer (on transfer of flag); and F. Cock, to the *Thunderer* (on becoming ship of Senior Officer, Reserve Fleet, Devonport).

Surg. Lt.-Comdr.: S. R. Johnson, appt. to R.N. Sick Quarters, Dartmouth (cancelled).

Surg. Capt. E. Sutton to be Surg. Rear-Admiral.

Surg. Capt. H. C. Whiteside assumes charge of the R.N. Sick Quarters at Shotley Boys' Training Establishment, and Surg. Capt. L. M. Morris is appointed to Haslar Hospital.

Surg. Capts.: R. F. Clarke to the *Vivid*, addl., for R.N. Barracks, Devonport; J. H. Fergusson to the *President*, addl., for three months' post-graduate course (on relief); E. Cameron to the *Cardiff*, as Squadron Medical Officer; and W. N. Blatchford to the *Pembroke*, addl., for R.N. Barracks, Chatham.

Surg. Lts.: J. Gaston, to the *Ajax* (on becoming ship of Senior Officer, Reserve Fleet, the Nore); and A. C. Esmonde, to the *Centurion*, for Squadron duties (on transfer of flag).

F. B. Quinn to be Surg. Lt.

ROYAL AIR FORCE.

F. T. Boucher is granted a short service commission as a Flight Lt.

INDIAN MEDICAL SERVICE.

Maj. P. K. Gilroy has been appointed to act as Senior Surgeon, Jamsetje Jaghibhoy Hospital, Professor of Surgery, Grant Medical College, and Presidency Surgeon, First District, Bombay. Capt. B. F. Eminson has been posted for general duty to St. George's Hospital, Bombay. Major R. H. Candy acts as Civil Surgeon, Hyderabad (Sind); Lt.-Col. R. F. Steel, Civil Surgeon, Ahmednagar, acts as Civil Surgeon, Poona; and Capt. E. T. N. Taylor acts for him at Ahmednagar.

VIENNA MEDICAL FACULTY.—The thirteenth international Course of Lectures in Medicine will take place in Vienna from June 16th to 29th inclusive, the subject being the Latest Developments in Surgery, Orthopædics, Urology, Gynæcology and Obstetrics, to be followed by a course of clinical instruction from June 30th to July 5th. A full programme may be obtained from Prof. Dr. A. Tischel, Dean of Vienna Medical Faculty, Universität, 1, Ring des 12. November, Vienna.

Medicine and the Law.

CRIMINAL RESPONSIBILITY: LORD DARLING'S BILL.

A BILL "to declare and amend the law relating to the criminal responsibility of accused persons" has been introduced in the House of Lords by Lord Darling and appears likely to become the law of the land before very long. It is a short measure containing only two effective sections, the first of which introduces an important and the second an unimportant alteration in the law under which a person alleged by those defending him to have been insane when he committed a criminal act may be found "guilty but insane."

Section 1, Subsection (1) of the new Act, if the Bill passes unaltered, will provide that "a person is not responsible to the law for an act or omission charged against him as a crime, if, at the time of doing the act or of making the omission, he is proved to be suffering from such a state of mental disease as deprives him (*a*) of capacity, at the time, to know, understand, and appreciate the physical nature and quality of the act done or omission made; or (*b*) of capacity to know, understand, and appreciate at the time that the act done or omission made was wrong." This is evidently intended to crystallise in the form of a statutory enactment, with somewhat different phraseology, the rule laid down by the judges in McNaghten's case, under which the defence must prove, in order to establish a plea of insanity, that "at the time of the committing of the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or if he did know it, that he did not know he was doing what was wrong." It will be observed that, as in the rule that has hitherto prevailed, the Bill speaks of knowledge that the particular act done was "wrong." It does not suggest a general power to distinguish right from wrong, or to appreciate what is or is not unlawful. In this and other respects it appears neither to add to nor to detract from the effect of the rule in McNaghten's case.

Subsection (3), however, introduces a change long advocated by members of the medical profession, and suggests that observations of Lord Darling and other judges, when confronted with the suggestion of an "uncontrollable impulse" on the part of a prisoner before them, may have been due to a desire to administer the law as it stood, rather than to an uncompromising admiration of its effect. Paragraph (*c*) of Subsection (1) has for its object to render the accused not responsible to the law:—"If at the time the act was done or omission made he was suffering from such a state of mental disease as therefrom to be wholly incapable of resisting an impulse to do the act or to make the omission." It may be pointed out here that the mental disease must be such as not merely to weaken the power to control the impulse, but wholly to do away with it.

Subsection (2) of Section 1 deals with one of the points raised in McNaghten's case, the question of the weight to be given to delusions on the part of the prisoner in determining his responsibility. It provides as follows: "A person who is suffering from mental disease at the time of doing the act or of making the omission charged against him as a crime, and by reason of such mental disease is affected by delusions on some specific matter or matters, but whose mental condition does not render him irresponsible to the law within the meaning of Subsection (1) of this section, is criminally responsible for such act done or omission made to the same extent as if the facts with respect to which such delusions exist were real."

In McNaghten's case the judges were of opinion that "notwithstanding the party did the act complained of with a view, under the influence of insane delusion, of redressing or revenging some supposed grievance or injury, or of producing some public benefit, he is nevertheless punishable, according to the nature of the crime committed, if he knew at the time of committing such crime that he was acting contrary to law." The principle appears to be the same—that is to say, the delusions are not to be taken into account, as by themselves excusing an act which otherwise would constitute a crime. The Bill, however, ignores the suggestion that appreciation of the illegality of the act committed should form a test of responsibility.

Section 2 has for its object the substitution of a verdict of "not guilty on the ground of insanity," for that of "guilty but insane," now returnable under Section 1, Subsection 2, of the Trial of Lunatics Act, 1883. The change has often been advocated. It is obviously illogical to declare a man guilty and at the same time to absolve him from the usual consequences of an act for which guilty intent is essential.

The alteration of the wording of the verdict will make no difference to the manner of dealing with the person as to whom it is found, for only the subsection of the Act of 1883 referred to above is to be repealed by the new measure, for which the title "Criminal Responsibility (Trials) Act, 1924," is proposed, and which is not to extend to Scotland or Northern Ireland.

HARNETT *v.* BOND AND ADAM IN THE COURT OF APPEAL.

THE trial of the action brought by Mr. W. S. Harnett against Dr. C. H. Bond and Dr. G. H. Adam, arising out of the confinement of the plaintiff in various asylums, following a visit to the office of the Commissioners in Lunacy, when released on probation from Malling Place, where he had been under the care of Dr. Adam, was reported in THE LANCET of March 8th, p. 511. The appeal of the defendants, who asked for judgment or for a new trial, was heard by Lords Justices Bankes, Warrington, and Scrutton, the arguments of counsel occupying seven days. In the appeal Sir Douglas Hogg was added to the counsel who appeared for Dr. Adam, and Sir John Simon led for the respondent Harnett. The Attorney-General, Sir Patrick Hastings, as before, led for Dr. Bond.

It will be remembered that the jury gave the following answers to questions submitted to them:—

1. Did Dr. Bond cause the plaintiff to be detained at the office until the attendants came for him?—Yes.

2. Did he cause him to be sent back for the purpose only of his being examined by Dr. Adam or for the purpose of his being detained at Malling Place?—Being detained at Malling Place.

3. Did Dr. Bond cause the plaintiff to be taken back?—Yes.

Did he and Dr. Adam agree, after consultation, that the plaintiff should be sent for and taken back?—No.

Was the taking back entirely the act of Dr. Adam?—No.

4. Was the plaintiff of unsound mind on Dec. 14th, 1912?—No.

Was he fit to be at large?—Yes.

Was he dangerous to himself or to others?—No.

5. Did Dr. Bond honestly believe that the plaintiff was of unsound mind, not fit to be at large, and dangerous to others?—No.

6. Did he believe that the plaintiff had escaped from his brother's charge; and, if so, was that his reason for having him sent back?—Yes.

7. Did he take reasonable care to ascertain the true facts?—No.

8. Did he honestly believe that Dr. Adam had retained the power of retaking the plaintiff during his 28 days' leave of absence?—Yes.

9. Did Dr. Adam, when he received the telephone message and sent his car, honestly believe that the plaintiff, on Dec. 14th, 1912, was of unsound mind and unfit to be at large?—Yes.

10. Did he honestly believe that it was in the plaintiff's interest that he should be taken back to Malling Place?—Yes.

11. Did he take reasonable care in doing what he did?—No.

12. Did he make it known to the plaintiff that he was liable to be retaken if his mental condition required it?—No.

13. Was the detention of the plaintiff at the Commissioners' Office the act of Dr. Bond alone, or was it really the act of both defendants?—Dr. Bond.

As to damages, the jury awarded £25,000 against the defendants jointly, apportioning £17,500 as against Dr. Bond, and £7500 as against Dr. Adam. In the event of the defendants being held to be liable only for the detention of the plaintiff by Dr. Adam they awarded £7500 against Dr. Bond and £2500 against Dr. Adam, and alternatively for the detention of the plaintiff by Dr. Bond at the Commissioners' office, £5000 against Dr. Bond. Judgment on these findings was eventually entered by Mr. Justice Lush for £5000 against Dr. Bond, and £20,000 against him and Dr. Adam jointly.

In opening the appeal on behalf of Dr. Bond, the Attorney-General referred to the extreme importance of the case, judgment having been given against Dr. Bond for £25,000 on the ground of his alleged responsibility for the whole period of the plaintiff's detention, the important effect of which must be that no medical man would ever again certify a man whom he believed to be insane, if, that is to say, in the event of his being found to have been negligent, he was to be held responsible at law for all damages that flowed therefrom. The relevant evidence, counsel said, was that which showed the state of the plaintiff's mind on and about Dec. 14th, 1912, when he went to the office of the Commissioners in Lunacy. Going through the whole of the evidence as to the state of Mr. Harnett's mind, the Attorney-General dwelt upon the details of his visit to Dr. Bond, bringing with him a bag containing £30, and displaying it as an inducement to Dr. Bond to send with him at his expense an official to prevent his brothers and his wife from carrying out a plot against him. The effect of the judgment would be that doctors would decline to certify, and the country would be flooded with lunatics who ought to be in asylums. The grounds of appeal were (1) that the verdict was against the weight of evidence; (2) misdirection; (3) that the damages were excessive; (4) that the damages given were not recoverable as they were too "remote." The long detention of Mr. Harnett was not the direct consequence of the act of Dr. Bond, but followed upon a *novus actus interveniens*, consequently the £20,000 damages were "too remote," and, further, on the verdict of the jury, the judgment for £20,000 jointly against the two defendants could not stand, as the answers of the jury (see answers 1, 3, 13) negatived a joint liability. The relevant evidence showed the plaintiff to have been temporarily insane at the material time.

Mr. Harold Morris, K.C., following for Dr. Bond, read the judgment in the court below, and submitted that it was for the jury to determine what share each defendant took in the prolonging of the period of detention. Dr. Bond had taken no part in the matter after Dec. 14th, and had had judgment for £20,000 jointly entered against him.

Lord Justice Bankes observed that there was no verdict against Dr. Adam for £20,000, but one for £25,000; yet there had been judgment against him for £2000. The court had to decide which of alternative findings by the jury was right in law.

In the course of further argument Lord Justice Bankes called attention to answers (see 3 and 9) as to Dr. Adam's belief as to the plaintiff's condition, and, further, to the necessity for ascertaining whether there was evidence that Dr. Bond did not honestly believe the plaintiff to be of unsound mind. Cases cited as to the question of *novus actus interveniens* were Weld-Blundell *v.* Stephens (36 *Times* L.R., 640; [1920] A.C., 956); Ward *v.* Weeks (7 Bing., 211); Parkins *v.* Scott (1 H. and C., 153).

Sir Douglas Hogg, opening the case for Dr. Adam, submitted three points for consideration: (1) that the burden of proof that Dr. Adam acted without reasonable care lay on the plaintiff; (2) that in any case Dr. Adam had acted with reasonable care when he sent a motor-car for the plaintiff on Dec. 14th; (3) that Mr. Justice Lush ought to have told the jury that the criterion of reasonable care on the part of Dr. Adam was "what were the facts reasonably known to him when he received the telephone message from Dr. Bond?" He cited cases Williams *v.* Beaumont (10 *Times* L.R., 343); Shackleton *v.* Swift ([1913] 2 K.B., 304). He went on to say that it must be borne in mind that it was not an uncommon result of a patient being allowed to go out of an asylum on leave that he should have a relapse. It seemed to have been assumed also at the trial that once a patient was received in an asylum he never got out of it again. The jury was misdirected when told they might take into account events following on the drive back to Malling Place. Subsequent detention was due to the view formed by Dr. Adam after the patient was returned to his care. The only tort alleged against Dr. Adam was his having the plaintiff brought back to Malling Place, and there was no finding of the jury as to damages due in respect of that act.

Sir John Simon, opening the case for the respondent, Mr. Harnett, proposed to deal with it separately as against (1) Dr. Bond, (2) Dr. Adam. Certain alleged wrongful acts were done either in agreement between the two or in the alternative by one or other of them. The plaintiff's case was that he was sane on Dec. 14th, 1912. His mental illness was caused by an injection of tuberculin which had produced toxic insanity, but not a mental disease. His religious mania had passed, and he was cured by Dec. 12th when he left the home. It was an extraordinary coincidence that when he finally escaped he should then be admittedly sane. The act of imprisonment for which Dr. Bond was responsible went on until there was a *novus actus interveniens*. The probation order had created for the plaintiff the status of a free man until revoked, which it had never been; and when once the jury had found that the plaintiff's condition did not require his detention, it followed that his imprisonment by Dr. Bond extended beyond the time for which he was kept in the Commissioners' offices, so that the jury were entitled to award damages in respect of it. There was no *novus actus interveniens* and no defence to the action as far as Dr. Bond was concerned. As against him the jury could take into consideration at least the period up to November, 1913 (when the plaintiff left Malling Place).

Sir John Simon proceeded to argue that the whole of the procedure adopted by Dr. Adam under the probation order was wrong. He could not revoke it on receipt of a telephone message. Steps should have been taken to re-commit the plaintiff to the asylum under Sections 15 and 16[1] of the Lunacy Act, 1890, which, counsel contended, though primarily intended to apply to persons not before certified, were wide enough to cover the case of a patient on probation. There had been no independent medical testimony as to the plaintiff's condition as required by the Act, and no independent investigation before a judicial officer. Dr Adam's action constituted a trespass *ab initio*. He was not protected by Section 330 of the Lunacy Act, 1890, as the jury had found that he had acted without reasonable care. The onus was upon him to prove that he had acted with such care, and there was ample evidence to support the jury's finding. Sir John Simon laid stress on the evidence that Dr. Adam only saw the plaintiff a few hours after his return, and argued that the jury had to consider his conduct at the relevant time. Mr. Harnett had been found by the jury not to have been then insane, and there had been a joint tort at a certain period committed by the two defendants. There was no ground for construing the probation order as conferring upon them a power of arrest.

---

[1] Sections 15 and 16 relate to the duties of constables, justices, and medical practitioners in connexion with the reception and detention in asylums of pauper and other lunatics "wandering at large."

Mr. J. B. Matthews, following on behalf of the appellant, Mr. Harnett, said that Dr. Adam had relied in his pleadings on Section 330 of the Lunacy Act, 1890,[2] but was not entitled to do so as he knew the Commissioner had no right to arrest, and that he himself had no right to send keepers to arrest, the plaintiff. A *novus actus interveniens* to be relied upon must be something coming from the outside, therefore what Dr. Adam did was not a *novus actus interveniens* so as to protect Dr. Bond, as they were joint tort feasors. Nor was Dr. Passmore, to whose care Mr. Harnett was consigned later, a *novus actus*, as the business had been "framed up" and Dr. Passmore's mind poisoned against the plaintiff.

Counsel relied upon Chamberlain *v.* King (L.R. 6 C.P. 474), Griffith *v.* Taylor (2 C.P.D. 194), Hermann *v.* Seneschal (13 C.B., N.S. 392).

Sir John Simon then submitted further that omission to discover the true condition of the plaintiff could not constitute a *novus actus interveniens;* that if the *novus actus* put forward was induced by the defendants' own action it would not protect them; there might be more than one cause of an act being done, and one such cause might be the conduct of the defendants. In that case, so far as the defendants were concerned, the *actus* would not be *novus.* Sir John Simon referred to Pollock on Torts, 12th edn., p. 240; Ratcliffe *v.* Evans [1892] 2 Q.B., p. 430 (a passage in a judgment by Lord Justice Bowen).

Mr. Harold Morris, replying on behalf of Dr. Adam, referred to Section 55[3] of the Act, and argued that in its true meaning it authorised the medical officer of an asylum to decide whether a patient, released on a probation order such as that under discussion, should be brought back. If that view was correct Dr. Adam was protected, and if he had committed no tort there could be no joint tort by him and Dr. Bond.

Sir Douglas Hogg, replying on behalf of Dr. Bond, contended that in the Lunacy Act, 1890, the words "take" and "retake" are used in contradistinction to "receive," and that they were used in the Act in such a way as to justify the course pursued in the case of the plaintiff. That course was adopted under sections contained in Part II. of the Act which was distinct from Part I., the latter providing for the care of lunatics at large and their certification, whereas Part II., containing Section 55, related to care and treatment after reception. Reports after reception were made by experts, and were not judicial inquiries such as were directed by Part I. The onus of proof of want of reasonable care, Sir Douglas Hogg contended (citing Williams *v.* Beaumont and Duke (10 *Times* L.R. 543)), was upon the plaintiff. There was no want of reasonable care on the part of Dr. Bond in the taking back of the plaintiff to Malling Place, or on the part of Dr. Adam in acting upon what was said to him by the Commissioner in Lunacy.

The arguments of counsel having been concluded, Lord Justice Bankes intimated that the Court would not deliver judgment until after the Easter vacation.

---

[2] Section 330 protects from civil or criminal proceedings on the ground of "want of jurisdiction or any other ground" any person who has done anything in pursuance of the Act provided he acted "in good faith and with reasonable care."

[3] Section 55 relates to the "Absence on Trial for Health" of a patient and gives powers to the manager of a hospital, or licensed house, to permit absence on trial, subject to conditions which include the consent of a commissioner.

THE LATE DR. A. M. ADAMS.—Dr. Alexander Maxwell Adams, of Tibshelf, who died recently at the age of 60 years, was son of the late Mr. A. M. Adams, F.R.C.S.E., of Friarsfield, Lanark, and belonged to a well-known medical family in Scotland. Dr. Adams was educated at Lanark Grammar School and at Edinburgh University, where he graduated M.B., C.M. in 1884. His first post was that of sub-curator in the Pathological Museum of Victoria University, Manchester, after which he had some experience of general practice in Scotland. Later he became Protectorate Surgeon in Gambia, West Africa, and engaged in research work on sleeping sickness, publishing the results of his investigations in 1903, when their merit was recognised by a diploma of the First Class bestowed on him by the University of Palermo, Italy.

Correspondence.

"Audi alteram partem."

THROMBOSIS, PULMONARY AND ELSEWHERE.

To the Editor of THE LANCET.

SIR,—We must all have read with much interest the full discussion on pulmonary thrombosis, embolism, and allied conditions, held at Liverpool on March 14th and reported by you on April 12th.

Concerning the clinical distinction between pulmonary thrombosis and embolism, I think there is rarely, if ever, any difficulty. An embolism always (?) causes instant distress, panting, dyspnœa, and often hæmoptysis. Thrombosis, rapid as it may be, is gradual. A case which I witnessed a few years ago may be worth recording.

I was asked by a colleague to see with him a case of acute pneumonia in a man of middle age. It was a case of some severity, and we met two or three times until crisis having occurred normally I took my leave with words of congratulation to the patient and his friend. It was in a humorous spirit that, on bidding my medical friend good-bye, I said you will have no more need of me unless the patient gets a clot in his pulmonary artery. A day or two later (I have no notes, unfortunately) my colleague telephoned to me that all seemed well but that the patient "felt bad." On further inquiry I was told that the pulse was 82, the respirations easy, and the temperatures normal. This seemed so reassuring that I replied that I hoped no more was the matter than a reaction from severe illness. However, in a day or two again my friend telephoned that the symptoms were still as before, but that the patient still said that he "felt bad." I was not definitely requested to visit the patient again (he lived some distance away), and on the record given I hoped he would soon recover his strength and spirits. In another day or two the telephone gave the same message. The patient still "feels bad," please come over at once.

On my arrival one saw at once he *was* "bad." He was sitting up in bed, not panting, but distressed, a little ashen in colour, and he had the appealing look of a man in dread. Still temperature normal, respirations not obviously hurried—say 18 to 20—pulse of excellent quality—82—and heart-sounds normal. Nothing definitely abnormal to be heard in the lungs. An invalid diet was taken as usual. There was no doubt about the diagnosis of thrombosis. Carbonate of ammonia was pressed in doses as large as possible, but no hope of recovery could be given. For about two days more the patient remained much the same—no worse; then as the nurse was counting the pulse—it was still 80 and quite regular—he turned suddenly over and died, the pulse stopping on the instant under her finger. The autopsy went no farther than to reveal a dense pale clot in the pulmonary artery. During its formation the patient must have lived at least seven or eight days; while the only tell-tale was his aspect, which was unmistakable. It was something like that of angina, but there was no pain.

May I now say a few words on thrombosis of the limbs in infections and septic conditions? In ordinary practice nowadays we see little of the infectious fevers, but I am thinking of days, not very long ago, when typhoid fever was frequent, and further back to a time when I had entire charge of the Leeds Fever Hospital. Thrombosis of the veins of the legs was no rare accident, less frequently of an arm; sometimes we had to deal with the far more grievous event of thrombosis in the popliteal or femoral artery. These accidents were events of convalescence, especially of the early stage of it. Now one of the first reliefs to which such a patient looks forward is to turn, or be turned, to lie upon his side, or at least to lift one leg over the other, or to turn so as to lie upon an arm. Thereupon pressure falls on a blood-vessel, slows its current, and a clot may ensue. Then and since I have given strict orders to nurses to shift such patients, or to let them shift themselves only with very careful precautions, such as the insertion of a soft pillow between the legs, and the like. By these means thrombosis of the limbs could always be prevented. As I have never seen this point of practice mentioned in any book or essay, I have ventured to quote my own experience.

We used to read of thrombosis of the cerebral sinuses in chlorosis; I say "used to," because for some unexplained reason chlorosis is a disappearing malady. I remember one case only of this thrombosis. I was called by a medical friend to a large Yorkshire house in consultation on a young woman in chlorosis —a "classical" case. Our opinion, both as to prognosis and cure, was hopeful and confident. Two days later the patient died, almost suddenly, of encephalic thrombosis—a mishap which was not placed to the credit either of my colleague or of myself. I think these cases were very rarely seen at any period of history.

I am, Sir, yours faithfully,

Cambridge, April 15th, 1924. CLIFFORD ALLBUTT.

MALTA FEVER AND EPIZOÖTIC ABORTION.

To the Editor of THE LANCET.

SIR,—In an annotation on this subject, which appeared in THE LANCET of Feb. 9th (p. 297), reference is made to the similarity between the causal organisms of these diseases and to the fact that in America a case of Malta fever has been identified in a patient who "had never been abroad, nor for a long time outside the city of Baltimore, and had had no contact with goats," and from whom a strain had been isolated belonging to the abortus subspecies. It is stated in your annotation that "we have here, then, apparently *for the first time*, an example of variation in the pathogenic relations of this organism." (The italics are mine.) I venture to draw your attention, therefore, to a paper [1] entitled Infectious Abortion of Cattle and its Possible Relation to Human Health, which I read before the Southern Rhodesia Veterinary Association on Nov. 12th, 1921, and which terminated with the following summary of conclusions:—

1. The disease known as infectious abortion of cattle, which exists in Southern Rhodesia, is caused by the *B. abortus* of Bang, and serological tests indicate that it is identical with the specific abortion of cattle in other parts of the world.

2. The *B. abortus* of Bang bears a close morphological and biological resemblance to the *M. melitensis*. Serological tests also indicate a close affinity, in that certain strains of *M. melitensis* can be agglutinated with serum from cattle infected with infectious abortion, and strains of *B. abortus* can also be agglutinated by serum from human patients suffering from undulant fever.

3. The characteristic symptom of undulant fever in goats and sheep is abortion.

4. Certain cases presenting symptoms resembling undulant fever have occurred in Southern Rhodesia in men who, as far as is known, have not obtained infection from goats, but have resided on farms where animals are, or have been, infected with infectious abortion.

5. It is suggested that these cases are suffering from an infection caused by the *B. abortus* of cattle.

6. It is also suggested that human females may contract infectious abortion through the ingestion of the organism in milk and dairy products from infected cows.

7. Although infectious abortion is prevalent in other parts of the world where goats' milk is not used for human consumption, it has not been accused of causing the symptoms of undulant fever in man, nor has it been proved to cause abortion in human subjects.

8. Although infectious abortion has prevailed in the Marandellas district for many years, it is only within the last few months that cases resembling undulant fever in man have been recorded.

9. While circumstantial evidence points to the infection of man by the *B. abortus* of Bang, and scientific tests up to a point support this suspicion, the final proof is not yet available.

10. If infectious abortion is essentially a bovine disease, a grave responsibility attaches to the Veterinary Department, and if this disease is communicable to man, a hearty coöperation between the medical and veterinary professions is necessary in dealing with it.

Since this article was written cases have continued to occur in this country under similar circumstances, but, strange to say, it generally happens that only one member of the family becomes infected—sometimes the husband, sometimes the wife, and occasionally a child or a visitor. In one instance it was the unfortunate mother-in-law who, during a short visit, contracted the disease, while the other members of the family remained healthy. Such circumstances do not point to infection through the milk, but no explanation is at present forthcoming as to why certain individuals are susceptible or how the infection of cattle can become virulent to man.

Although from recent literature on the subject it would appear that veterinary authorities do not consider the danger a real one, I would suggest that if members of the medical profession would apply the agglutination test to the blood of those suffering from the obscure pyrexias referred to in the annotation, or of their female patients suffering from sterility or abortion, evidence might be obtained that epizoötic abortion of cattle is another of the numerous diseases of animals communicable to man; and far more dangerous than is generally believed.

I am, Sir, yours faithfully,

LE E. W. BEVAN,
Director of Veterinary Research, Southern Rhodesia, S.A.
March 20th, 1924.

*** In *Public Health Reports* for March 14th, 1924, appears an interesting survey of what is known of human infections with *B. abortus*, by Miss A. C. Evans. There seems to be no doubt that such occur, partly as illnesses resembling Malta fever, more frequently as unrecognised infections leaving serological evidence in the form of specific agglutination. Many people are exposed to infection through drinking raw cows' milk in which the organism of contagious abortion is not uncommon.—ED. L.

DOCTORS AND ADVERTISING.

To the Editor of THE LANCET.

SIR,—In your issue of March 29th Dr. Harold Spence agrees with the suggestion I made in a letter appearing in your columns on March 1st, that the public have no easy and reliable method of obtaining information regarding specialists in venereal disease, that consequently they are liable to fall into the hands of pseudo-specialists, and that a register of specialists under the various diseases or branches of medicine—giving details of work and record on which such special experience is based—is desirable. I made no suggestion regarding *selection* of names of persons qualified to "style himself a specialist," and certainly did not suggest that "only those who maintain a hospital connexion are eligible to be described as specialists."

I cannot agree with Dr. Spence that it would be right or proper for the General Medical Council to decide who was or was not entitled to call himself or herself a specialist in any disease. All I suggested was that an easily accessible register should be drawn up containing the names of *all* medical practitioners practising in special branches of their profession, together with full details of their work and experience in these particular fields. The public would then be in a position to judge for itself, and would have sufficient data to enable it to select the professional help it required.

I am, Sir, yours faithfully,

H. WANSEY BAYLY.

Harley-street, W., April 19th, 1924.

INSULIN BY THE SKIN AND MOUTH.

To the Editor of THE LANCET.

SIR,—Major H. H. King will find in THE LANCET of Oct. 6th, 1923 (p. 777), that a negative result was obtained by my colleagues and myself after administering insulin per rectum in a case of diabetes. The necessary control experiments were carried out.

I am, Sir, yours faithfully,
London, W., April 15th, 1924. E. P. POULTON.

CERTIFICATES OF INSANITY.

To the Editor of THE LANCET.

SIR,—I share with Dr. Suttie the view that it may be sought to enact that certificates shall be shown to patients under care and treatment in virtue of such documents. This view is based, so far as I am concerned, firstly on one of the suggestions contained in a letter by a critic of lunacy administration to *The Times* of March 17th, which I ventured to examine in your issue of March 29th; and, secondly, upon a legal attitude disclosed in the recent trial before Mr. Justice Lush, from which it appeared that it was regarded as surprising and even monstrous that certificates were not as a matter of course shown to patients. My submission is that in many cases to do so would be futile and in others injurious, but my objection to a general enactment that certificates should be shown to patients does not commit me to the opinion that there are no cases in which they might be shown.

I am, Sir, yours faithfully,
E. D. MACNAMARA.
Harley-street, W., April 15th, 1924.

THE WASSERMANN REACTION IN DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—The recent correspondence in these columns by Dr. J. N. Cruickshank and Mr. H. Wansey Bayly shows how important it is that the true diagnostic value of the Wassermann reaction (W.R.) should be definitely ascertained. The crux of the whole matter would appear to lie in the rightness or wrongness of Mr. Bayly's statement that "it is now . . . established that a positive reaction does not necessarily mean that the individual is syphilitic." Dr. Cruickshank is of the opinion that, so far as the new-born infant is concerned, the test is of no value whatever. On the other side, is Dr. L. W. Harrison's view that "provided that the test is carried out according to the principles of the original method, a definitely positive result indicates that the person is suffering from syphilis." He, however, enumerates some 15 non-syphilitic conditions in which positive results have been reported as occurring, and he indicates that these may be possible exceptions.

In considering these positive reports from non-syphilitic patients, two factors must be taken into account: (1) The technique by which the test was performed, and (2) the certainty with which syphilis could be ruled out in the person from whom the blood was taken. The first is of the utmost importance; and a survey of the literature on this matter for the last decade demonstrates clearly that as technique has improved the number of reports of non-specific reactions has markedly decreased. At the present day one is inclined to regard such reports as either an indication of faulty technique, or that the person from whom the serum was obtained was suffering from endosyphilis. Malaria, for example, is alleged to be capable of giving a positive W.R. In McConnell's case of malaria which ended fatally[1] the patient's blood during life gave a positive result, although clinical signs and a history of syphilis were absent. At the autopsy, however, very definite syphilitic lesions were found in the aorta. Had a post-mortem not been done, and had the diagnosis of syphilis not been made microscopically, this case would undoubtedly have taken its place among those quoted in support of the statement that malaria can produce a positive W.R.

A considerable proportion of syphilitics present no clinical signs whatever, and may even show a negative serological picture until the application of certain stimuli—e.g., iodides, a provocative injection of arsenobenzol, pregnancy, or some febrile disease. If clinical signs of the disease cannot be demonstrated, if a syphilitic history is unobtainable (and a negative history is valueless), and if a positive W.R. is not accepted, then the only way in which syphilis can be diagnosed or eliminated is by a histological examination of the wall of the left ventricle, the aorta, the testicles, pancreas, and suprarenal capsules. The post-mortem diagnosis of syphilis depends upon finding the specific histological mild inflammatory picture, consisting of lymphocyte and plasma-cell infiltrations in the stroma surrounding the blood and lymphatic vessels, particularly in the organs and tissues indicated. Strictly speaking, therefore, in no case of alleged non-specific positive W.R. can syphilis be eliminated unless it has come to the post-mortem table and proved negative on microscopic examination. Warthin[2] holds that a positive W.R. indicates syphilis except in a few rare cases of generalised malignant disease, and he finds that this view is confirmed by post-mortem findings.

The diagnosis of post-mortem syphilis which rests upon the gumma is obsolete. The histological picture of syphilis is specific, and it is due to the local action of the *Treponema pallidum* which has undergone some regression in virulence. The stimulus of iodides, arsenobenzol, or malaria is capable of rejuvenating these organisms, of enhancing their virulence, and thus producing a positive W.R. in the blood. Marcialis[3] gives the results of an investigation of the Wassermann and Sachs-Georgi reactions in 225 cases of malaria. Only 2·2 per cent. gave positive results which might possibly be attributed to malaria on the grounds that there were neither clinical signs nor any history of syphilis. But these, since they did not come to necropsy, cannot, in view of the experience of Warthin and of McConnell, be definitely declared to be non-syphilitic.

The disappearance of a positive W.R. in an infant soon after birth is, of course, a common observation even without anti-specific treatment, and it only means that the condition of endosyphilis has occurred. The practical danger of it is that the unwary may be tempted to cease treatment, or to refrain from commencing it, under the impression that the child is not syphilitic. Such an infant may present none of the usual stigmata until the occurrence of, say, interstitial keratitis after puberty. It is an appreciation of this which impels one to the view that, no matter what may be the serological condition at any time after birth, the anti-syphilitic treatment of a child born with a positive W.R. must extend at least till adolescence. The only sure criterion of cure in syphilis is that the individual again acquires a primary chancre. The only real evidence of the absence of syphilis is the failure to find the specific histological appearances after death. These tests are of little use to the living patient, so that practically we are left with the W.R.

There can be no doubt but that clinical experience and pathological investigation show that there is no more specific test in medicine than the W.R., and that the margin of error is less than 0·3 per cent. As syphilis does exist without clinical signs, there can be no avoiding the conclusion that at the very least the presence of a positive W.R. entitles the patient to the benefit of the doubt, and the expression of that is the institution of prolonged anti-syphilitic treatment.

I am, Sir, yours faithfully,
Manchester, April 18th, 1924. E. T. BURKE.

SCHICK IMMUNISATION IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—When the Schick test and immunisation against diphtheria is being discussed, attention is concentrated on its use to prevent diphtheria among school-children or adults such as nurses in fever hospitals. Might I be allowed to point out the extreme importance of the test and immunisation being carried out for very young children, such as those attending infant welfare centres? In London 52·6 per cent. of the 2846 deaths occurring from diphtheria in the three years 1919–21 took place in children under five years of age.

I am, Sir, yours faithfully,
C. W. HUTT, M.D.,
Medical Officer of Health, Metropolitan Borough of Holborn.

ELECTRIC LIGHTING AND EYESTRAIN.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 19th, 1921, you published part of my introduction to a discussion at the Royal Society of Arts dealing with Kinematographic Illumination and Eyestrain; it has occurred to me that there may be some connexion between alternating current lighting and eyestrain, which probably accounts for some preferring a type of lighting other than electric; whereas, with direct current lighting the discomfort is apparently non-existent. In my own case, I find it is far more comfortable for my eyesight when working under direct current lighting in my office as compared with alternating current lighting in my private residence.

It would be interesting to hear the experience of surgeons when conducting delicate operations under these two different conditions—alternating *v.* direct—as with alternating it is possible to detect several images of bright metallic instruments especially when these are in motion, similar to "cinematograph" action. This "cinematograph" effect is most pronounced in the low-wattage "Neon" night-light bulbs when used on an alternating current circuit. Perhaps ophthalmic surgeons could throw some light on the apparent increase in the use of spectacles in certain areas.—I am, Sir, yours faithfully,

J. C. ELVY, A.M.I.E.E., M.I.E.S.,
Consulting Engineer.
12, Tavistock-street, Strand, W.C. 2, April 10th, 1924.

⁂ With an alternating current, an arc lamp or a "Neon" lamp goes out every time the current reverses, but very few people work by the light of such lamps. With incandescent electric lamps, on a circuit with less than 25 alternations per second, there is a perceptible flicker in the light which undoubtedly is trying to the eyes. We understand that while there are 25 cycle plants operating on power loads which also supply lighting, there is no authority supplying alternating current at less than 50 alternations per second for lighting. But even at this speed there may be a slight cyclic variation in the light, especially from the low-power high-voltage metal filament incandescent lamp, in which the mass of the filament and therefore the stored heat energy is very low. The point is one which ophthalmic surgeons might consider.—ED. L.

MASSIVE DOSES OF DIGITALIS IN AURICULAR FAILURE.

To the Editor of THE LANCET.

SIR,—Dr. J. Jensen's short paper on this subject, published in your issue of April 12th, should serve to draw attention to a really valuable and even life-saving measure. Since the work by Eggleston and his colleagues, to which Dr. Jensen refers, showed that these large doses were safe, I have been in the habit of using a modification of their method very similar to that described by Dr. Jensen. The plan turns on the capacity of the average adult patient with auricular failure to take 3 drachms of the tincture of digitalis in the first 24 hours of treatment, if the symptoms are urgent enough to call for drastic means of relief. Dr. C. E. K. Herapath and I, in a paper on auricular failure read at a recent meeting of the Bristol Medico-Chirurgical Society, gave some account of our experiences of this plan. We have never seen any ill-effect from these large doses, while, on the other hand, we have known lives saved which would have been lost unless this plan had been followed.—I am, Sir, yours faithfully,

Clifton, Bristol, April 14th, 1924. CAREY F. COOMBS.

A CRITICAL EXAMINATION OF PSYCHO-ANALYSIS.

To the Editor of THE LANCET.

SIR,—I have read Dr. R. M. Riggall's letter to THE LANCET of April 5th. Before entering upon a controversy Dr. Riggall ought, above all, to make himself acquainted with the facts.

On p. 189 of my book I said: ". . . the facts upon which Janet's and Breuer's methods are based are, I believe, beyond dispute, but I am not concerned here with their theories. They have, however, little in common with Freud's psycho-analytic method, which was modelled upon Breuer's cathartic method. Neither am I concerned here with the dangers that arise from the bringing back into consciousness of old-forgotten memories, as is done in the cathartic method, and I shall therefore not dilate upon this subject. Suffice it to say that some authorities have pronounced themselves against this method in no equivocal manner."

Your reviewer remarked upon this that I had given no reference for the terminating statement and I therefore mentioned in my letter to THE LANCET Binswanger, whose work on hysteria was and remains a standard work on the subject. I might have given many more names, English, German, or French if I had troubled to look up references, but I thought one recognised authority would be more effective than a long string of names of lesser lights. From the above quotation it is perfectly clear that I do not take sides with reference to "abreaction" (which, by the way, was not Freud's idea, but Breuer's) and concerning this question I would direct Dr. Riggall's attention to the symposium on "The Revival of Emotional Memories and it Therapeutic Value" in the *British Journal of Psychology*, Medical Section, 1921, vol. i., pp. 16–33.

It is further evident from the above quotations that this point does not affect the main thesis of my book. I endeavoured to show that the very foundations of the psycho-analytic doctrine and its means of penetrating the "unconscious" are unscientific and fallacious, and in this I have apparently been successful, for psycho-analysts never join issue upon this main thesis, but invariably try to side-track the discussion upon unessential details.

I am, Sir, yours faithfully,
Shortlands, Kent. A. WOHLGEMUTH.

THE CENTENARY OF FRIEDRICH WILHELM BENEKE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 12th, p. 781, it is stated that Prof. Beneke, the centenary of whose birth has just been celebrated at Bad Nauheim, was for several years chief physician to the German Hospital in London. This is not quite correct. He was house physician at the hospital from January, 1849, to the summer or autumn of 1851, and then practised his profession in Hanover. He afterwards became professor at the University of Marburg, and also took a great part in the development of Bad Nauheim. He died in December, 1882. My father succeeded him in 1851 as house physician to the German Hospital in London.

I am, Sir, yours faithfully,
London, W., April 14th, 1924. F. PARKES WEBER.

Obituary.

RICHARD JAMES REECE, C.B., M.D. Camb.,

SENIOR MEDICAL OFFICER, MINISTRY OF HEALTH.

We deeply regret to announce the sudden death on Easter Sunday of Surgeon-Colonel R. J. Reece, which occurred in his sixty-first year, at his country house, Basketts, Birchington.

Dr. Reece was born in Kensington and educated at the Kensington School, St. Bartholomew's Hospital, and Downing College, Cambridge, whence he graduated as M.B. in 1892, later proceeding to the M.R.C.P. Lond. and the Cambridge doctorate. He was also one of the earliest holders of the D.P.H. of the Conjoint Board. He held the resident surgical posts at St. Bartholomew's Hospital, being also ophthalmic house-surgeon, and quite early in his career published some interesting clinical notes both in these columns and in the St. Bartholomew's Hospital Reports. He joined the medical staff of the Local Government Board in 1892, under Sir Richard Thorne Thorne, and from that time onwards his admirable epidemiological and sanitary work has been at the disposal of the Government, first at the Board and later at the Ministry of Health, where at the time of his death he was senior medical officer. As medical inspector of the Local Government Board he was the author of many valuable reports on small-pox, cholera, enteric fever, cerebro-spinal fever, and acute poliomyelitis, while past experience in the service of the City and Port of London indicated the consignment to him of many administrative questions in connexion with the work of port sanitary authorities. His intensive study of the outbreak of epidemic poliomyelitis, which occurred in Cornwall and Devon 12 years ago, brought his name prominently to the front as a scientific observer of the highest class, as well as an administrator of courage and firmness. The outbreak occurred in the neighbourhood of Holsworthy in August, 1911, when the medical officer of health, Dr. W. G. Gray, recognised that certain cases of so-called "spotted fever" were occurring over a wide area but attracting very little attention, and when the initial neglect enabled the disease to spread from Bude on the west to Hartland, Swimbridge, South Molton, and eventually Tavistock, Dr. Reece was sent down by the Local Government Board to make a special investigation, and, owing to his pressure, the Holsworthy Urban Council realised the necessity for taking efficient measures. At first the council declined to provide for the isolation of cases—and there was difficulty in the accommodation of these—but Reece attended one of the sessions of the Council and informed the members that an infectious disease "that killed people" was at their doors, and that there were probably 30 cases at the moment inside their own district, while infection had extended to other districts in the neighbourhood.

When the war broke out Reece almost immediately received an appointment on the headquarters staff of the Army Medical Service, for he had been since boyhood a member of the H.A.C., giving him the official right to the now rare designation of Surgeon-Colonel. His work during the war in the administration of preventive services in regard to infectious diseases was remarkably thorough, particularly in regard to cerebro-spinal fever, which in the second and third year of the war was prevalent in various parts of the country. His accurate knowledge here was of particular value, because the disease was one of which we had little previous experience, and it proved so variable in its manifestations that mistakes in diagnosis were constantly being made. In a paper communicated to The Lancet in March, 1917, Reece published, at the request of the Medical Research Committee, a series of notes on five cases which were primarily thought to be cerebro-spinal fever, but which proved ultimately to be acute anthrax. Confusion in the detection of cerebro-spinal fever, as apart from acute poliomyelitis, tuberculous meningitis, influenza, typhoid, and rheumatic fevers had undoubtedly often arisen, but anthrax as a further difficulty in diagnosis had not previously been observed, and these notes were a valuable contribution to clinical medicine. His knowledge of small-pox and vaccination questions was profound, and in recent years the present system of control over small-pox in England was directed by him and by the medical officers in his section at the Ministry of Health. This, like all his other work, he undertook with untiring industry, with a high sense of duty, and with pride in his department. Reece's position as an epidemiologist and sanitarian was recognised by his election and re-election to preside over the Epidemiological Section of the Royal Society of Medicine; he was vice-president of the Public Health Section of the British Medical Association at the important Glasgow meeting in 1922, and had examined in State Medicine at his old University. He received the C.B. (Mil.) for his services during the war.

Surgeon-Colonel Reece's sudden death will be felt by a large circle of personal, official, and professional friends, by whom he was both admired and respected for his attainments and social qualities.

HUGH WALSHAM, M.D. Camb., F.R.C.P. Lond.

Dr. Hugh Walsham, consulting radiologist to St. Bartholomew's Hospital, who died in London on April 13th, was a pioneer worker in medical radiology. Born in 1856, the second son of William Walker Walsham, of Wisbech, Cambridgeshire—his elder brother being the surgeon, Mr. W. J. Walsham, who died in 1903—Hugh began his education at King's College, London, proceeding to Caius College, Cambridge, where he graduated in medicine and surgery in 1887. His medical student days were spent at St. Bartholomew's Hospital. In the City of London Hospital for Diseases of the Chest he obtained the post of pathologist in 1894, and two years later he was appointed physician to the out-patient department of the hospital. The same year he was also appointed assistant medical officer to the electrical department of St. Bartholomew's Hospital. Profiting by his experience at these two hospitals, he was one of the first to realise the uses to which X rays might be put in investigation of diseases of the chest. By examining patients clinically and radiologically and by making X ray pictures of the cadaver in cases which came to autopsy he was able to correlate clinical and radiological findings. The book which he wrote, under a joint authorship with Dr. Harrison Orton ("The Röntgen Rays in the Diagnosis of Diseases of the Chest," published in 1906), was the first on the subject to appear, and may be regarded as the original classic. His essay on the Channels of Infection in Pulmonary Tuberculosis had gained the Weber Parkes Prize three years earlier.

Walsham was chief assistant in the electrical department of St. Bartholomew's Hospital when the late Dr. Lewis Jones was medical officer in charge. He conducted all the radiological work of the department while Lewis Jones devoted his time to the study and practice of electro-therapeutic work. In 1912, the year after the retirement of Lewis Jones, radiology was made the work of a new department and separated from the original electrical department, and Walsham was elected medical officer in charge and lecturer on radiology. "Before he retired from active work at the hospital," one of his colleagues writes, "Walsham was a familiar figure in the X ray room. Always bright and cheery, he was ever ready to assist those in need of help in the interpretation of radiograms. Although his work became more arduous year by year—two rooms only were allotted for the X ray work of the entire hospital—he would always spare time to those who sought his help. During the last months in which he was in charge of the X ray department he was frequently absent on account of ill-health, which eventually compelled him to retire. During the latter years of his life

Walsham kept aloof from medical meetings, and it is probable that the majority of the younger radiologists never even saw him."

On his retirement from the department Dr. Walsham was appointed consulting radiologist to St. Bartholomew's Hospital. Relieved from routine hospital duties, he continued private work until the illness which terminated his life. Like other pioneer workers in radiology, Dr. Walsham was the victim of X ray burns and had lost several of his fingers. His own experience led him to hold the view strongly that medical officers and nurses should only be attached to X ray departments for limited periods.

RICHARD HINGSTON FOX, M.R.C.S. ENG., M.D. BRUX., F.R.C.P. LOND.

Dr. Hingston Fox, whose death took place at Jordans Village, Beaconsfield, after a short illness on April 20th, came of Quaker medical stock, being descended from a line of doctors practising in the West Country. Born at Stoke Newington in 1853, he was the third of six surviving sons of Joseph John Fox, surgeon, all of whom followed the family tradition and entered the medical profession. From an early age Fox Tertius became a companion and helper to his father. His medical course was taken at the London Hospital, where he won scholarships in scientific subjects and whence he qualified M.R.C.S. and L.S.A. in 1874. Ten years later he took the M.D. Brux. and the M.R.C.P. Lond. His Fellowship was conferred upon him the year before his death.

After qualification Dr. Hingston Fox was for a number of years in general practice at Finsbury Park, at the same time steadily acquiring a city connexion in Finsbury-square. Like some other physicians who have not been closely attached to hospitals he made a study of life assurance, and more than 40 years ago was appointed medical officer in London to the Friends' Provident Institution, an appointment which he held to the end of his life. His statistical bent and philosophic outlook fitted him well for this class of work, and he was one of the first to take a broad view of adolescent albuminuria. At the Assurance Medical Society, of which he was one of the original members, his contributions were frequent and welcome; he was for many years its foreign correspondent and was elected to the presidential chair. At the Hunterian Society he held in succession all the chief offices, and his oration on the life of William Hunter was published later in book form. At the time of his death he was just completing the centenary history of the Society. Medical history always occupied much of his time and thoughts. In 1919 appeared "Dr. John Fothergill and his Friends" (Macmillan), in which the facts and references were compiled with such care as to make the book an intimate picture of medical and social life in the eighteenth century. In his own words, this work was intended as a reminder "of what our fathers were thinking and doing in times of strain and battle and loss, albeit on a lesser scale than ours," and he hoped that it might help some to meet the age-long questions that beset the lot of humanity.

In 1902 Dr. Fox gave up general practice and moved to Gordon-square. A few years later his health, never very robust, led to the surrender of his city practice, and he took rooms in the Harley-street district, where he enjoyed a considerable general consulting practice, living in succession at Hampstead, Golders Green, and Jordans Village. On the transfer of the Friends' Provident Institution to London he became its chief medical officer. He was also medical examiner for the U.K. Provident Institution, hon. physician to St. Luke's Provident Dispensary, and, during the war, assistant physician to Mount Vernon Hospital for Consumption.

To his acquaintances Dr. Fox appeared cautious, retired, unassuming, deliberate of speech, and wise in judgment; his friends knew that behind his manner of reserve lay warm feelings and a quick insight. Outside his profession his personal interests were catholic. His knowledge of botany, geology, and ornithology was unusually complete. Bible study was only second with him to medical study; his shelves were full of Latin, Greek, Hebrew, and Persian volumes, and he welcomed the higher criticism as an aid to reverent knowledge. He was no mere acquirer of facts, but sought to integrate and re-interpret them, writing his own translations of Hebrew and Greek texts. Never idle for a moment, his poor health seemed to limit but little his mental output. In his early manhood he was threatened with phthisis, but his health was then restored by voyaging to the Antipodes as ship's surgeon. Later in life he suffered from disabling attacks of Ménière's disease, but at these times continued to read and write on his couch. His death was due to an acute attack of intestinal obstruction.

Dr. Fox married in 1879 Elizabeth, daughter of the late Charles Tylor, and had seven children, all of whom survive him. His only son, Dr. J. Tylor Fox, is medical superintendent of the Lingfield Epileptic Colony.

ALBERT EDWARD MORISON, M.B., C.M. EDIN., F.R.C.S. EDIN., M.R.C.S. ENG.

Mr. A. E. Morison, hon. surgeon to the Sunderland Royal Infirmary, died suddenly at his own house, St. George's-square, Sunderland, on April 9th, at the conclusion of his consulting hour. He was 61 years of age. Mr. Morison was educated at King William's College, Isle of Man, and he graduated in medicine and surgery at the University of Edinburgh in 1884, taking his M.R.C.S. Eng. in 1886 and F.R.C.S. Edin. in 1889. He joined his brother, Dr. James Rutherford Morison (afterwards professor of surgery in Durham University), in partnership at Hartlepool in 1884 and took over the practice when his brother moved to Newcastle. About 16 years ago Mr. Morison went to commence consulting practice in Sunderland and later to live in that town, at the same time maintaining the closest connexion with the Hartlepools. During the whole of his life he was actively associated with Hartlepool Hospital, and at the time of his death was the senior and an active member of its staff. He was following most keenly the schemes for hospital development at present engaging the attention of the management of that institution. On his coming to Sunderland he became associated with the Sunderland Royal Infirmary and Children's Hospital. He was appointed honorary assistant surgeon in 1909, and honorary surgeon five years later. He retired in accordance with the age rule and was appointed honorary consulting surgeon in 1922. He was chairman of the nursing committee 1920–22, and took the keenest interest in the nursing question and did much to raise the standard of efficiency. During his association with the Royal Infirmary he had a great deal to do with the organisation of workmen's contributions.

Mr. Morison took part in the Boer War in South Africa, and during the late war, with the rank of major in the Royal Army Medical Corps, he served overseas for certain periods. He was especially identified with the Northumberland War Hospital, the Sunderland War Hospital, and the Hamerton House V.A.D. Hospital in Sunderland. A feature of his work being his skill in bone surgery, he was appointed surgeon specialist in head injuries to the Northern Command. After the war he became surgeon to the Sunderland Pensions Hospital. He was always keenly interested in medical politics and presided at different times over the Northumberland and Durham Medical Society and the North of England branch of the British Medical Association.

About two years ago Mr. Morison's health gave rise to anxiety and he took a long holiday; this, characteristically, he spent in visiting America, where he studied the hospital work of that country, giving valuable communications on the subject when he returned. His professional life was a very full one. He was a surgeon of great skill and natural genius, but the outstanding feature of his life was his work for the youth of Hartlepool—this town was the first (in England) to undertake a Boys' Brigade, and Mr. Morison threw himself heart and soul into the work from the beginning. Dr. "Bertie," as he was affectionately called, was Captain, 1st Hartlepool Company Boys' Brigade for many years. He also initiated and was president of the Hartlepool Old Boys' Institute, which dealt with those boys who had passed through the Brigade and had reached the age limit.

A funeral service was held in Christ Church, Sunderland, on Saturday, April 12th, when there was a large attendance, many of the doctors of Sunderland being present and also representatives of many local activities. After the service the body was conveyed by motor to Hartlepool, where another service was held at St. Hilda's Church. The scene in Hartlepool was most remarkable and impressive, practically the whole town attending the funeral and paying a last tribute to one who had been the devoted friend of the boyhood and youth of Hartlepool for 37 years.

In 1896 Mr. Morison married Miss Harriet Appleby, eldest daughter of the late Mr. Thomas Appleby, J.P. He leaves a widow, a son, and two daughters.

Medical News.

UNIVERSITY OF LONDON.—An advanced lecture in ophthalmology on Accommodation will be given at the Charing Cross Hospital Medical School, Chandos-street, W.C. 2, by Dr. J. Van Der Hoeve, professor of ophthalmology in the University of Leiden, at 5 P.M., on Friday, May 9th. The chair will be taken by Mr. E. Treacher Collins. The lecture will be delivered in English and illustrated by lantern slides. Admission is free.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The Oliver-Sharpey lectures will be delivered by Prof. A. V. Hill on Tuesday, April 29th, and Thursday, May 1st, at 5 o'clock. The subjects will be: (1) The Recovery Process in Isolated Muscle, and (2) the Recovery Process in Man. On Monday, May 5th, at 5 o'clock, Dr. Karl F. Wenckebach, professor of medical pathology and therapeutics, and director of the First Medical Clinic, Vienna, will deliver a lecture on Angina Pectoris and the Possibilities of its Surgical Relief.

An extraordinary Comitia of the Royal College of Physicians of London was held on Monday, April 14th, at 5 P.M., the President, Sir Humphry Rolleston, Bart., being in the chair. The President delivered the annual address and pointed out that there were now 371 Fellows, compared with 87 a hundred years ago. The roll of the College now showed 636 Members and 14,902 licentiates. He referred to the death of the late Bedell, Mr. William Fleming, who had served the College for more than 50 years, 31 years as Bedell. He read obituary notices of the 12 Fellows deceased during the past year—namely, Dr. A. C. Latham, Sir James Reid, Dr. G. E. Rennie, Dr. P. W. Latham, Dr. P. W. Saunders, Prof. D. W. Finlay, Dr. Thomas Henry Green, Dr. Lauriston E. Shaw, Dr. Thomas W. Thursfield, Dr. Donald W. C. Hood, Dr. W. A. Wills, and Dr. Alexander Haig. Sir Humphry Rolleston was then re-elected President by 67 votes out of 69. Reports were received from the Committee of Management as follows:—

The Committee of Management recommend that Clause 3, Section II., of the regulations relating to the pre-medical examination which is as follows:—

(3) Candidates who produce satisfactory evidence that they have passed an examination in chemistry and physics or in chemistry or physics which exempts them from further examination in one or both subjects for the Degree in Medicine of any University in the British Empire, or of a Foreign University recognised by the Examining Board in England, will be exempted from the subject or subjects in which they have passed.

be revised so as to read:—

(3) Candidates will be exempted from the pre-medical examination who produce satisfactory evidence: (*a*) of having been registered as medical students by the General Medical Council: or (*b*) of having passed a preliminary examination in general education recognised by the Examining Board in England, and a pre-medical examination in chemistry and physics conducted by any of the qualifying bodies whose degrees or diplomas are registrable on the Medical Register; or (*c*) of having passed an examination in chemistry and physics for the Degree in Medicine or Science of any University in the British Empire or of any Foreign University recognised by the Examining Board in England.

A report was received from Dr. R. A. Young, the visitor appointed to inspect the examinations of the Egyptian Medical School and Hospital, Cairo, and the present conditions of teaching in the Medical School and Hospital, and certain recommendations for transmission to the Minister of Education of the Egyptian Government were adopted.

The Committee of Management report that they are satisfied that the conditions laid down by the Royal Colleges for the recognition of the Welsh National School of Medicine, Cardiff, have now been fulfilled, and they recommend that the Welsh National School of Medicine, with the Cardiff Royal Infirmary, be included in the permanent list of institutions recognised by the Conjoint Board.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—On April 28th Mr. V. E. Negus will lecture on New Points in the Mechanism of the Larynx; on April 30th Prof. W. E. Gallie will lecture on the Transplantation of the Fibrous Tissues in the Repair of Anatomical Defects; and on May 2nd Mr. H. Ernest Griffiths will lecture on Further Relationships of Diseases of the Gall-bladder to the Secretory Functions of the Stomach and Pancreas. All these lectures will be held at 5 P.M. at the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following candidates have passed the Final Dental Examination and have been granted the diploma L.D.S. R.C.S. Edin.:—

Archibald Matthew, Charles F. Mummery, John A. Watt, John Brown, Robert S. Matthew, Henry N. McKenzie, John C. Shiach, Gavin J. Bell, Harry B. Kyle, Cameron F. Murdoch, David D. Radford, James Hughes, John Murphy, James B. Kerr, John S. MacHardy, John Campbell, Robert Bell, Frederick A. Hunter, George M. Brigg, Agnes M. E. Wilson, Thomas Jamieson, Stuart J. Beaton, Orry S. Crowthers, George R. Moffoot, Edward N. Jamieson, Francis Mackenzie, Lesslie Macduff, and James Brydone.

MIDDLESEX HOSPITAL MEDICAL SOCIETY.—The 150th anniversary special meeting of the society will be held at the Middlesex Hospital on Thursday, May 22nd, at 8.15 P.M., when Sir James Kingston Fowler will deliver an address entitled Links with the Past. After the address there will be an exhibition of objects of historical interest to the Middlesex Hospital, and pathological and bacteriological exhibitions.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A number of post-graduate courses have been arranged for April–May, and copies of the syllabus can be obtained from the Secretary, 1, Wimpole-street, W.1. Commencing on Monday, April 28th, is a two weeks' intensive course at the Hampstead General Hospital, comprising clinical daily work in medicine and surgery with a formal lecture or lecture-demonstration every afternoon. In association with this hospital demonstrations, &c., will also be given at the Paddington Green Children's Hospital and the North-Western Fever Hospital. From April 28th to May 10th will be held a short course in dermatology at the Hospital for Diseases of the Skin, Blackfriars, including instruction each afternoon from 2.30, and a venereal clinic twice a week from 5.30 P.M. At the Maudsley Hospital, Denmark Hill, a month's course in Psychological Medicine will be held from May 5th to 30th. The course will consist of lecture-demonstrations on various aspects of Mental Diseases. The various facilities of clinical instruction at the hospital will be open to those attending the course. As already mentioned, a comprehensive course in Venereal Diseases will be held at the London Lock Hospitals (Dean-street and Harrow-road) from May 5th to 31st. The course will include clinical work every day in the wards and out-patients' department, and a lecture on some branch of the subject will be given each day at 91, Dean-street, W. 1. At the Central London Ophthalmic Hospital from May 5th to 31st a series of lecture-demonstrations on subjects of interest to the specialist as well as to the general practitioner will be given in Ophthalmology, and, if desired, an Operative Surgery class can be arranged for. A fortnight's course in Proctology will be held at St. Mark's Hospital for Diseases of the Rectum from May 12th to 24th, consisting of operations, demonstrations, and lectures by members of the staff. Also beginning on May 12th and continuing until the 24th will be given a course on Infants' Diseases at the Infants Hospital The comprehensive syllabus covers clinical demonstrations, "round table" consultations, lectures, &c. An intensive course in Laryngology, Rhinology, and Otology will be held at the Central London Throat, Nose, and Ear Hospital from May 12th to 30th. A programme comprising clinical demonstrations, lectures, &c. has been arranged for from 9.30 A.M. to 5 P.M., and for those desiring it an Operative Surgery class will be available. The special intensive course to be given from May 19th to 31st at the North-East London Post-Graduate College (Prince of Wales's General Hospital), Tottenham, will include demonstrations of clinical methods and cases, &c. The 4.30 P.M. formal lectures will be free to general practitioners.

INDIAN MEDICAL SERVICE DINNER FUND.—The annual dinner of the Indian Medical Service will be held at the Trocadero on Wednesday, June 18th, Colonel J. J. Pratt in the chair. Tickets and all particulars may be obtained from the honorary secretaries, 63, Addison-road, Kensington, W. 14.

Dr. H. B. Brackenbury has been awarded the gold medal of the British Medical Association "for his arduous and distinguished services to the Association and the medical profession."

EUGENICS EDUCATION SOCIETY.—A lecture on State Certificate of Marriage will be delivered by Dr. R. A. Gibbons at the rooms of the Royal Society, Burlington House, Piccadilly, on Friday, May 2nd, at 8.30 P.M. Major Leonard Darwin will be in the chair.

FOUR lectures on the Brain and the Mind will be delivered by Sir Robert Armstrong-Jones at Gresham College, Basinghall-street, London, E.C., on Tuesday, April 29th, April 30th, May 1st, and May 2nd, at 6 P.M. Admission is free.

MANCHESTER ROYAL INFIRMARY.—Sir John Bland-Sutton, President of the Royal College of Surgeons of England, will give the Lloyd Roberts lecture at the Manchester Royal Infirmary on Oct. 7th. His subject will be Attic Salt for Gall-stones.

LEICESTER ROYAL INFIRMARY.—At the annual meeting of the infirmary on April 16th Mr. C. J. Bond, vice-president of the infirmary, who presided, spoke of the necessity of establishing coöperation between the voluntary hospital, the municipal infectious diseases hospital, the mental hospital, the Poor-law infirmary, the sanatorium, the tuberculosis dispensary, and the school clinic in every area. It would be also necessary, he said, to spread the work done by the members of the present honorary staffs of voluntary hospitals over a larger section of the medical profession, and sufficiently remunerate the work performed and the services rendered so as to do away with that unhealthy competition between public hospital work and private practice, which was now exercising an injurious effect not only on the medical profession itself, but on the interests of the hospitals and the public.

A USEFUL NURSING DIRECTORY OF LONDON.—Hospital almoners and others who desire to secure home nursing for cases of sickness in the poorer districts of London will be glad to know that the directory, compiled and issued in 1917 by the Central Council for District Nursing, has now been reissued with a supplement which brings up to date the information as to the appropriate nursing association for every street in London. Some 30,000 streets and places lying within the County of London are included in the directory, which has also an index giving the names and addresses of all the recognised district nursing associations and a reference number indicating the association to which application should be made for nursing help in any particular street. Telephone numbers are also given. The directory has already proved a most useful aid to social workers and hospital officials, as well as to doctors. The price has been fixed at 2*s*. 6*d*. (or 2*s*. 9*d*. post free), which is half the actual cost of production, in order to make the information more readily accessible. Copies can be obtained from the Secretary-Visitor, Central Council for District Nursing in London, 20, Cockspur-street, London, S.W. 1.

ST. MARY'S HOSPITAL: INSTITUTE OF PATHOLOGY AND RESEARCH.—A course of lectures on Pathological Research in its Relation to Medicine has been arranged for the summer session. These lectures will be given in the lecture room of the Bacteriological Department of the Institute on Thursday afternoons at 5 P.M. On April 24th Sir Almroth E. Wright, F.R.S., gave the first lecture on the Anti-Bacterial Functions of the Leucocytes. On May 1st Sir Thomas Lewis, F.R.S., will lecture on Reactions of the Skin to Injury. On May 8th Prof. A. V. Hill, F.R.S., will discuss the Function of Hæmoglobin in the Body, and on May 15th Dr. Andrew Balfour will deal with Some Medical and Sanitary Lessons. On May 22nd Dr. Major Greenwood will give a lecture entitled Is the Statistical Method of any Value in Medical Research? On May 29th Dr. Gordon M. Holmes will lecture on the Ductless Glands and Personality. On June 5th Mr. Wilfred Trotter will speak on the Sensibility of the Skin in Relation to Neurological Theory, and on June 12th Prof. William Bateson, F.R.S., will give the final lecture on the Determination of Sex. These lectures are open to all members of the medical profession and to all students in medical schools without fee.

DONATIONS AND BEQUESTS.—Under the will of the late Alderman H. E. Lawrence, of Lee, Kent, the St. John's Hospital, Lewisham, will receive £1500, and the Blackheath and Charlton Hospital and the Miller Hospital £100 each.—The Chelsea Hospital for Women has received £100 from the Goldsmiths' Company for the Nurses' Home.—An anonymous bequest of £10,000 has been made to the Royal Society for the prosecution of original research in medicine for the prevention of disease and the relief of suffering, with special attention to tropical diseases in British possessions, cancer, and tuberculosis.—Under the will of the late Colonel J. S. Tait, of Edinburgh, the Kilmarnock Infirmary will receive £500, and the Glasgow Deaf and Dumb Institution and the Glasgow Asylum for the Blind £100 each.

QUEEN'S UNIVERSITY (BELFAST) CLUB, LONDON.—The first dinner of this club was held in the Connaught Rooms, London, on April 10th. Colonel Thomas Sinclair occupied the chair. The company, composed of Belfast graduates and their guests, numbered close on 150. Many members from Liverpool, Manchester, Portsmouth, Bath, and the Midlands were present. Enthusiastic speeches, in tribute to the Alma Mater and in support of the club, made by the chairman, Lord MacDonnell, Sir Lynden Macassey, Prof. J. A. Lindsay, and Mr. R. W. Livingstone, Vice-Chancellor of the University, were much appreciated. There were also present Sir David Semple, Sir W. Maxwell, Colonel R. McCarrison, Rev. D. Wilson, Mr. J. R. Fisher, K.C., Dr. James Chambers, and Dr. W. Douglas. A musical programme added greatly to the enjoyment of the evening. Altogether the reunion was a most happy and successful one. To mark his year of office, the President kindly presented a Gold Challenge Cup to the club. Members wishing to compete for this trophy should at once communicate with Mr. A. McKinstry, 4, Central Buildings, Westminster, London, S.W.

ROCKEFELLER MEDICAL FELLOWSHIPS.—The Rockefeller medical fellowships for the academic year 1924–25 will be awarded by the Medical Research Council in June, and applications should be lodged with the Council not later than May 31st. These fellowships are provided from a fund with which the Medical Research Council have been entrusted by the Rockefeller Foundation. Fellowships are awarded by the Council to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. A fellowship will have the value of not less than £350 a year for an unmarried fellow, with extra allowance for a married fellow, payable monthly in advance. Travelling expenses and some other allowances will be made in addition. Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 15, York Buildings, Adelphi, London, W.C. 2.

THE LANCET: SUBSCRIPTION RATES.

NOTES ON CURRENT TOPICS.

Criminal Responsibility Bill.

THE text has been issued of Lord Darling's Bill to amend the law relating to the criminal responsibility of accused persons suffering from mental disease. Clause 1 provides that (1) a person is not responsible to the law for an act of omission charged against him as a crime, if at the time of doing the act or of making the omission he is proved to be suffering from such a state of mental disease or disorder as deprives him (*a*) of capacity at the time to know, understand, and appreciate the physical nature and quality of the act done or omission made; or (*b*) of capacity to know, understand, and appreciate at the time that the act done or omission made was wrong; or (*c*) if at the time the act was done or omission made he was suffering from such a state of mental disease as therefrom to be wholly incapable of resisting an impulse to do the act or make the omission.

(2) A person who is suffering from mental disease at the time of doing the act or of making the omission charged against him as a crime and by reason of such mental disease is affected by delusions on some specific matter or matters, but whose mental condition does not render him irresponsible to the law within the meaning of Subsection (1) of this Section, is criminally responsible for such act done or omission made to the same extent, and as if the facts with respect to which such delusions exist were real.

HOUSE OF COMMONS.

TUESDAY, APRIL 15TH.

Conditions of Service in Mental Hospitals.

Mr. RAYNES asked the Minister of Health the hours and conditions of service of staffs employed in mental hospitals; whether they varied in different institutions, and, if so, for what reason; and, seeing that a 60-hour week was too long for people to be engaged in this class of service, would he take steps to secure a uniform basis of service and remuneration throughout Great Britain.—Mr. GREENWOOD (Parliamentary Secretary to the Ministry of Health) replied: The hours and conditions of service vary in public mental hospitals because they are determined by the visiting committees of the various local authorities by whom the hospitals are provided. Moreover, the conditions of the work vary to some extent in different institutions.

The Maternity Convention.

Sir ARTHUR SHIRLEY BENN asked the Minister of Labour what States had ratified the Maternity Convention drafted by the International Labour Conference at Washington in 1919.—Mr. T. S. SHAW replied: Bulgaria, Greece, Roumania, and Spain have formally deposited their ratifications of this Convention with the Secretary-General of the League of Nations, and I understand that its ratification has been recommended or authorised in certain other countries.

Fees of Post Office Medical Officers.

Sir EDWARD ILIFFE asked the Postmaster-General whether, in view of the fact that he had authorised postmasters to reduce the capitation fee paid to medical officers of the department to 11*s.*, that this reduced fee was fixed without consultation with the medical officers concerned, and that he authorised postmasters to advise medical officers at the end of March of this reduction, which was to be made retrospective to Jan. 1st, he would withdraw these reductions, which were at variance with the contracts.—Mr. VERNON HARTSHORN replied: It was part of the agreement reached with the British Medical Association in March, 1922, when the fee of 11*s.* 6*d.* was fixed, that the capitation fee for Post Office medical officers should be subject to review at the end of 1923, and this fact was made known to all medical officers at the time. The reduction from 11*s.* 6*d.* to 11*s.* was made in view of the fall in the cost of living since March, 1922, and is similar to that made from the same date and for similar reasons in the fee of doctors on the Health Insurance panels. The British Medical Association was informed of the proposed reduction as soon as it had been decided upon.

WEDNESDAY, APRIL 16TH.

Assessment of Invalided Naval Ratings.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty what course was open to an invalided naval rating whose invaliding disability was attributable to service and who was not satisfied with the degree of disability assessed by the Naval Medical Board.—Mr. AMMON replied: It is open to an invalided rating to appeal to the Board of Admiralty under whose directions the case would be reviewed in the light of any representations made on his behalf.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty whether it was the practice to make a reduction in the pensions of men invalided for non-attributable disabilities associated with specific disease; whether any scale of deduction existed; whether any disease other than venereal was included in the practice; and whether naval ratings generally were aware that such a practice existed, and under what legal sanction.—Mr. AMMON replied: The reply to the first part of the question is in the affirmative. The deduction made is considered on the merits of each case. A disease such as alcoholism would be included in the practice. The practice is sanctioned by the terms of Order in Council of Feb. 6th, 1922 (Statutory Rules and Orders, 1922, No. 132). These regulations have been published in Fleet Orders.

Notification of Births Regulations.

Lieut.-Colonel FREMANTLE asked the Minister of Health whether his predecessor in June of last year received a memorandum from the Central Midwives Board urging that the name of the person actually conducting the delivery of a child should be inserted in the form prescribed under the Notification of Births Act; and whether an alteration would be made in the form of notification of births accordingly.—Mr. WHEATLEY replied: The answer to the first part of the question is Yes. This suggestion will be considered in connexion with any proposed legislation amending the Notification of Births Acts or the Midwives Acts.

Maternal Mortality.

Lieut.-Colonel FREMANTLE asked the Minister of Health if he was aware that the maternal mortality-rate for England and Wales during the last 20 years has been maintained at or about 4 per 1000 births, but that in midwives' cases it was under 2 per 1000; and whether, in view of the dangers arising from unqualified persons attending women in childbirth he would introduce or support a Bill providing that no uncertified woman should attend women in childbirth except in an emergency or under the personal direction and in the presence of a registered medical practitioner.—Mr. WHEATLEY replied: As regards the first part of the question the facts are as stated in regard to the maternal mortality-rate for all cases, but I have no complete information as to midwives' cases. The suggestion in the second part of the question will receive consideration in connexion with any proposed legislation amending the Midwives Act.

League of Nations Opium Conference.

Mr. ORMSBY-GORE asked the Prime Minister whether the projected League of Nations Opium Conference had been convened for the purpose of giving effect to the principles submitted by the United States representatives on the Opium Advisory Committee last May; whether he was aware that those principles included the restriction of the use of opium and cocaine products to medical and scientific purposes, and the restriction of the production of raw opium to the quantity needed for such purposes alone; and whether the representative of His Majesty's Government on the preparatory committee for the Conferences would be instructed to give support to these proposals.—Mr. DAVIES (Under Secretary for the Home Office) replied: The purpose for which the Conference has been summoned is to consider the possibility of concluding an agreement or agreements for the limitation of the amounts of morphine, heroin, and cocaine to be manufactured, and the limitation of the amounts of raw opium and the coca leaf produced for export of the amounts required for such manufacture and other medicinal and scientific purposes, subject to an exception for those countries where opium-smoking is temporarily continued under Part II. of the Convention. The proposal that a Conference should be held with this object was put forward at the meeting of the Advisory Committee last May on behalf of the British Government, and the attempt to arrive at such agreements will receive the utmost support which the Government can give.

Diet in Casual Wards.

Mr. BRIANT asked the Minister of Health if he was satisfied that the diet allowed to inmates of casual wards was sufficient for the maintenance of health.—Mr. WHEATLEY replied: I am advised that the diet is sufficient for the purpose for which it is intended, but certain suggestions for making it more palatable are under consideration, and I hope for some improvement.

Government and the Spahlinger Treatment.

Mr. ALFRED T. DAVIES asked the Minister of Health whether he was aware that the New Zealand Government offered £50,000 to develop the Spahlinger treatment of consumption on the condition that the Ministry offered a similar amount; whether the Ministry had adequately investigated the results of such treatment; and whether any action was to be taken.—Mr. Wheatley replied: The answer to the first part of the question is No. As regards the second part, I may say that all such inquiries have been made by my department as have been practicable in the absence of a supply of Mr. Spahlinger's preparations for scientific investigation. As regards the third part, I am anxious to arrange for a scientific investigation of this method of treatment in this country, and have personally given Mr. Spahlinger assurances to that effect.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, April 28th.

ODONTOLOGY: at 8 P.M.

Casual Communications:

Mr. J. H. Badcock: The Prevalence of Supernumerary and Supplemental Teeth among the Natives of India (with examples contributed by Mr. C. H. Badcock, of Madras).

Paper:

Mr. J. Howard Mummery: The Nerve Distribution to the Dentine.

Thursday, May 1st.

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.

Annual General Meeting:

Election of Officers and Council for Session 1924–25.

Short Communications:

Prof. Louise McIlroy and Miss D. L. Leverkus: Changes in the Polarity of the Fœtus during the Later Weeks of Pregnancy.

Dr. George Graham: (1) The Effect of Pregnancy in a Patient with a Renal Glycosuria; (2) Report of a Case of Pregnancy Complicating Diabetes Mellitus, treated with Insulin.

Dr. Cuthbert Lockyer (President): A Case of Spontaneous Rupture of the Uterus.

Dr. H. Russell Andrews: An Unusual Case of Kidney Tumour.

Paper:

Mr. Alexander Galletly: Presacral Tumours of Congenital Origin, with a case in which a Cyst, complicating Pregnancy, was removed by the Abdomino-perineal Route.

Friday, May 2nd.

LARYNGOLOGY: at 5 P.M. (Cases at 4 P.M.)

Annual General Meeting:

Election of Officers and Council for Session 1924–25.

Cases and Specimens:

Cases and Specimens will be shown by the following: Mr. Norman Patterson, Dr. Aldington Gibb, Mr. Wharry, Dr. Dan McKenzie, and others.

ANÆSTHETICS: at 8.30 P.M.

Annual General Meeting:

Election of Officers and Council for Session 1924–25.

Paper:

Dr. Z. Mennell: Recent Experiences in America.

Saturday, May 3rd.

OTOLOGY: at 10 A.M. (Cases at 9.15 A.M.)

Annual General Meeting:

Election of Officers and Council for Session 1924–25.

Paper:

Mr. F. B. Gillespie: Aural Surgery at a Fever Hospital.

Cases and Specimens:

Dr. P. Watson-Williams: Case of Labyrinthine Vertigo due to Sphenoidal and Ethmoidal Sinusitis.

Other cases will be shown.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, April 28th, to Saturday, May 3rd.

Hampstead General Hospital, in conjunction with the North-Western Fever Hospital and Paddington Green Children's Hospital. Special Intensive Course.—Hospital for Diseases of the Skin, Blackfriars. Clinical instruction in the Out-patient Department every afternoon from 2.30 P.M. Tuesday and Friday, Venereal Clinic from 5.30 to 7 P.M.

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn-fields, W.C.

Monday, April 28th, 5 P.M.—Mr. V. E. Negus: New Points in the Mechanism of the Larynx.

Wednesday. 5 P.M.—Prof. W. E. Gallie: The Transplantation of the Fibrous Tissues in the Repair of Anatomical Defects.

Friday, May 2nd.—5 P.M., Mr. H. Ernest Griffiths: Further Relationships of Diseases of the Gall-bladder to the Secretory Functions of the Stomach and Pancreas.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

Tuesday, April 29th.—5 P.M., Prof. A. V. Hill: The Recovery Process in the Isolated Muscle. First Oliver-Sharpey Lecture.

Thursday, May 1st.—5 P.M., The Recovery Process in Man. Second Oliver-Sharpey Lecture.

UNIVERSITY COLLEGE, Gower-street, W.C.

(University of London Advanced Lecture in Hygiene.)

Friday, May 2nd.—5 P.M., Prof. Dr. C. Eijkman: Influence of Tropical Climate on Man. (To be given in English.)

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, April 28th.—2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. Simson: Diseases of Women.

Tuesday.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.

Wednesday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Dr. Pernet: Skin Dept.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

Friday.—11 A.M., Dr. McDougal: Electrical Dept. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital. (At 4.30 P.M.)

Monday, April 28th.—Dr. A. J. Whiting: Auricular Fibrillation and Flutter.

Tuesday.—Mr. C. H. Hayton: Œsophageal Growth, Treatment and Diagnosis.

Wednesday.—Dr. J. Browning Alexander: The Significance of Pleural Effusions.

Thursday, May 1st.—Mr. H. W. Carson: Diagnosis of Cancer of the Colon.

Friday.—Dr. C. E. Sundell: Dyspepsias of Childhood.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, W.

Tuesday, April 29th, 5.15 P.M.—Prof. Joseph Barcroft: The Effect of Altitude on Man (Lecture I.).

Saturday, May 3rd, 3 P.M.—Dr. F. A. E. Crew: Heredity and Sex (Lecture I.).

THE ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

Wednesday, April 30th, 5.30 P.M.—Dr. Charles Porter: The League of Nations Health Officers Interchange, in the United States.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

Thursday, May 1st.—Mr. Rivett: Normal Labour.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

Monday, April 28th.—(At the Children's Hospital.) Mr. W. A. Thompson: Pyloric Stenosis in Infants.

Tuesday.—(At the Southern Hospital.) Mr. Douglas Crawford: Surgical Cases.

Wednesday.—(At the Northern Hospital.) Mr. G. C. E. Simpson: Some Abdominal Cases.

Thursday, May 1st.—(At the Stanley Hospital.) Mr. J. T. Morrison: Swellings of the Knee-joint.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

Tuesday, April 29th.—4.15 P.M., Dr. E. B. Leech: Some Notes on Sanatoria and the Treatment of Tuberculosis.

Appointments.

Clark, C. A., L.D.S.R.C.S. Irel., has been appointed Honorary Consulting Radiologist to the Royal Dental Hospital.

Cowburn, A. D., M.R.C.S., L.R.C.P. Lond., D.P.H., Coroner for the Southern District of London.

Leapingwell, A. E., L.R.C.P. Lond., M.R.C.S., M.O.H., Certifying Surgeon under the Factory and Workshop Acts for Winslow.

Reid, W., M.B., Ch.B. Edin., Medical Superintendent, Burntwood Mental Hospital.

Smith, Norman F., B.M., B.Ch., M.R.C.S., L.R.C.P., Registrar, Kitchener School of Medicine, Khartoum.

Smith, R. Eccles, F.R.C.S. Edin., Honorary Surgeon to the Corbett Hospital, Stourbridge.

Wilson, Mary, M.B., Ch.B. Edin., Resident Medical Officer, Dundee East Poorhouse and Hospital.

Vacancies.

For further information refer to the advertisement columns.

Battersea Borough Council.—Part-time Asst. M.O. for Maternity work. £1 11*s.* 6*d.* per session.
Birkenhead and Wirral Children's Hospital, Woodchurch-road.—Hon. Radiologist.
Birkenhead Borough Hospital.—Third H.S. £100.
Cardiff, University College of South Wales, &c.—Prof. of Path. and Bact. £1500.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Reg. Out-Patients.
City of London Hospital for Dis. of Heart and Lungs, Victoria Park, E.—H.P. £125.
East Sussex County Mental Hospital, Hellingly.—Pathologist. £500.
Essex Administrative County.—Asst. County M.O.H. £700.
Exeter City Mental Hospital.—Asst. Med. Supt. £350.
Hemel Hempstead, West Herts Hospital.—Res. M.O. £200.
Home Office, Whitehall, S.W.—Woman Medical Inspector of Factories. £800.
Hospital for Consumption and Dis. of Chest, Brompton, S.W.—Asst. in Dept. of Pathology. £250.
Inverness Northern Infirmary.—Jun. Head Resident. £100.
Leeds General Infirmary.—Res. Ophth. O. £120. Also Ophth. and Aural H.S. £50.
London Lock Hospital, Dean-street and Harrow-road.—Surg. Reg.
London Temperance Hospital, Hampstead-road, N.W.—Med. Registrar. 40 guineas.
Loughborough and District General Hospital and Dispensary, 9, Leicester-road.—Res. H.S. £175.
Mid-Wales Counties Mental Hospital, Talgarth, Breconshire.—Asst. M.O. £350.
Newcastle-upon-Tyne Hospital for Sick Children.—Hon. Asst. S.
Pietermaritzburg, S. Africa, Grey's Hospital.—H.S. £400.
Queen's Hospital for Children, Hackney-road, E.—Asst. S. to Ear, Nose, and Throat Dept.
Royal Ear Hospital, Dean-street, Soho, W.—Hon. H.S.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. £175. Asst. R.M.O. £130.
Southampton Borough Isolation Hospital.—R.M.O. £360.
West End Hospital for Nervous Diseases, 73, Welbeck-street, W.—Cas. P. £200.
Whitehaven and West Cumberland Infirmary. — Res. H.S. £200.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Burghead, Morayshire; and Lavenham, Suffolk.

Births, Marriages, and Deaths.

BIRTHS.

HANCOCK.—On Easter morning, at Bexley, Kent, to Vera Primrose, wife of Dr. Allen Coulter Hancock, *M.C.*—a daughter.

HARTIGAN.—On April 10th, at the Royal Hamadryad Seamen's Hospital, Cardiff, the wife of Dr. J. Hartigan, of a daughter.

MOORE.—On April 15th, at Ickleton, Great Chesterford, Essex, the wife of Dr. J. York Moore, of a daughter.

PAVEY-SMITH.—On April 15th, at 9, Victoria-avenue, Harrogate, the wife of A. B. Pavey-Smith, *M.C.*, F.R.C.S., of a daughter.

ROCHE LYNCH.—On April 12th, at Sussex-place, Slough, the wife of G. Roche Lynch, M.B., of a daughter.

ROE.—On April 14th, at Ardington-road, Abington Park, Northampton, the wife of Robert Bradley Roe, M.R.C.S., of a son.

MARRIAGES.

PARRY—WILLIAMS.—On April 12th, at St. Andrew's, Leytonstone, R. Hughes Parry, M.B., B.S., D.P.H., to E. Joan Williams, L.R.C.P., M.R.C.S., eldest daughter of Mr. and Mrs. Percy E. Williams, of Wanstead.

DEATHS.

BARRETT.—On the 19th inst., at Le Havre, France, aged 64 years, Dr. William H. Barrett, of 29, Park-crescent, Southport.

DALTON.—On April 17th, very suddenly, Thomas Dalton, M.D., of Llandudno.

FOX.—On April 20th, at Jordans, Beaconsfield, R. Hingston Fox, M.D., F.R.C.P., aged 71.

OLIVER.—On April 14th, at Manningham-lane, Bradford, George Henry Oliver, M.R.C.S. Eng., D.O. Oxon., Senior Consulting Surgeon to the Bradford Royal Eye and Ear Hospital, aged 63.

REECE.—On Easter Day, at Birchington, suddenly, Richard James Reece, C.B., M.D., Senior Medical Officer Ministry of Health, late Surgeon-Colonel H.A.C., aged 61.

WALSHAM.—On April 13th, Palm Sunday, at Harley-street, Hugh Walsham, M.D., F.R.C.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE LIFE AND DOCTRINE OF SIR EDWIN CHADWICK.

By Sir William Job Collins, K.C.V.O., M.D., M.S., B.Sc. Lond., F.R.C.S. Eng.,
CHAIRMAN OF THE CHADWICK TRUST; PRESIDENT OF THE SANITARY INSPECTORS' ASSOCIATION.

(*Concluded from p. 834.*)

PART II.

Chadwick's Later Work.

DURING the 36 years which remained to Chadwick after the closure of his official life, he pursued, with little evidence of resentment and with the same ardour, the cause of sanitary and social reform. Pamphlets, presidential and other addresses, reviews and critiques came from his pen at frequent intervals, and these with his voluminous official reports cover a period of 60 years of continuous labour. These *disjecta membra* of what would compose a considerable library were collated and condensed by Richardson. Some 26 works of Chadwick's, including some cross references, appear in the British Museum catalogue. A yet more representative collection contained in some dozen volumes of pamphlets, essays, &c., are to be found in the library of University College. One can, in the time at my disposal, only touch lightly on these varied activities.

Chadwick coöperated with Miss Nightingale during and after the Crimean War in the reform, or rather the inauguration of military hygiene. He opposed taxes on knowledge and condemned the "fiscal rapacity" that restricted journalism and checked advertisement. He was a zealous advocate of competitive examinations for admission to the public service and the stout opponent of political patronage. One recalls the story of Melbourne when one of his ministers confessed to him that having to choose between two candidates for a valuable office, one a stranger and the other a relative, he proposed, *ceteris paribus*, to give it to his relative. "So should I," said Melbourne, "and damn *ceteris paribus*." He discussed the psychological and physiological limits of mental labour, the feeding of school-children, the physical and moral advantages of drill in school, and supported the volunteer movement. He was a member of the first London School Board, advocated baths in schools and adequate playgrounds. He emphasised the danger of spread of infectious diseases by schools and looked to physical training and sanitary surroundings "to banish epidemic and eruptive diseases." He was strongly opposed to corporal punishment, he condemned payment by results and the rigidity imposed by the code. He concerned himself with the construction of schools, suggested warming through hollow-tiled floors, advised double-paned windows, and left-lighting.

In a supplementary report in 1843 he had exposed the perils of interment in city churchyards, of delayed burial through lack of mortuaries to which the dead might be removed, pending interment, out of crowded homes, and endorsed Sir Christopher Wren's advocacy of cemeteries in the suburbs of towns. At Mr. Gladstone's suggestion he investigated and reported on the extension of cheap postal telegraphy.

Many of his addresses and essays were in English, which he wrote with ease; in 1864 he met Napoleon III. in Paris, who asked him what he thought of his improvements and he replied: "Sir, Augustus found Rome brick and left it marble; if your Majesty having found Paris stinking will leave it sweet you will more than rival the first Emperor of Rome." Common lodging-houses, as he found them, he described as schools for juvenile crime and vice and fertile agencies in propagating infectious disease, and recommended that they should be both licensed and inspected. From 1883-1889 he was President of the Sanitary Inspectors' Association, and his addresses were rightly regarded as among the chief sanitary events of the year.

Such varied instances as I have cited by no means exhaust the catalogue of his activities; as Richardson remarks, "his universality is unique." "He is found dealing with building construction as if he were an architect, with engineering as if he were an engineer. In treating of diseases he might often be taken for a physician, in matters of administration a politician, while he is always in his right place as a statistician." His wide knowledge of Government departments and their ways had led him to distrust the methods by which legislation is initiated and conducted, and in 1859 he read a paper on the subject before the Society for the amendment of the law. He condemned what he called the close Cabinet method of preparing Bills as well as Select Committee procedure, preferring open and deliberate inquiry by Royal Commissioners specially appointed for their competence and experience, or by a Committee of the Privy Council assisted as regards local inquiries by Sub-Commissioners. J. S. Mill and Sir James Stephen were supporters of these proposals. A little coterie of "friends in council" with Chadwick as the centre and Mill, Rowland Hill, Lyon Playfair, and Neil Arnott as members, met at each others' houses and were very active in the 'forties and 'fifties of last century in incubating plans for administrative reform and social betterment.

Parliamentary Candidature.

Richardson and the National Dictionary of Biography state that in 1867 Chadwick unsuccessfully contested London University for Parliament. He did indeed write an address to the electors, which was backed by J. S. Mill, but he did not go to the poll. I find from the Parliamentary Poll Book that Mr. Robert Lowe was returned unopposed in 1867 as the first member for the seat, which he retained for 12 years, and which Disraeli facetiously asserted he had created and predestinated for that erratic and unbeloved politician. Chadwick was, however, induced to come forward in 1868 for Kilmarnock Burghs and was beaten by the Hon. E. P. Bouverie by 2892 to 1148. The statement which he afterwards published in reference to his defeat betrayed his naïve and chagrined disillusion at the fickleness of electors, the delusiveness of public meetings, and the deceitfulness of political promises. He had indeed experienced a previous Parliamentary reverse at Evesham in 1859.

He also at one time coquetted with the electors of Southampton and of Middlesex, and to the latter issued an address intimating his willingness to come forward if assured of adequate backing, while disclaiming any intention of canvassing, attending meetings, or embarkiug on any expenditure beyond the official fees. The address dealt at length with metropolitan drainage, burial boards, extravagance and corruption in local administration, and advocated physical, educational, and moral improvement of the labouring classes and the "cutting up of political patronage by the roots." Such matter of fact doctrine and high ideals were, however, not calculated to split the ears of political groundlings. In short, you could not make a political hack or a safe whip's man out of Edwin Chadwick. He was ill-adapted for the platform, especially the political platform—in truth, he was no orator. Even the friendly Richardson wrote: "When he first gets up to speak without book he looks an orator; but a few moments dispel the illusion; he bends forward, he speaks in a low voice, he disputes some points logically, then falls into confusion, then recovers his strain, goes back, and, in fact, if he speaks long, as he is wont, he wearies the listener, and takes sometimes the points out of his own arguments."

His Political Philosophy.

In 1885, five years before his death, Chadwick sought to summarise and generalise the principles which had inspired his life's work and he published a collection of papers entitled "On the Evils of Disunity in Central and Local Administration" in which he took for his text the maxim of Bentham, "always to do the same thing in the same way, choosing the best, and always to call the same thing by the same name." These papers betray that diffuseness, repetition, and unattractiveness of style which his kindly biographer has deplored. He contended for larger areas than the parish for local administration, a responsible central supervisory authority, detailed administrative work to be discharged by competent salaried officers. He indicated how his principles which had inspired the Poor-law Amendment Act (1834) and his reports on the sanitary condition of the labouring population of Great Britain should be applied in the case of water-supply, smoke abatement, fire prevention and extinction, abattoirs, disposal of the dead, gas-supply, slum clearances, police administration, &c., and adumbrated the appointment and duties of a "Minister of Education" and a "Minister of Health." In the matter of the government of London he claimed that "the attainment of complete unity of administration would open up prospects of grievously needed relief"; while recognising that Sir Benjamin Hall's Act of 1855, which set up the ill-fated Metropolitan Board of Works, was a step in the direction of unification, he deplored the "vestralisation" whereby it was prejudiced owing to constitution by indirect election. It was partly to this congenital defect that Lord Herschell's Commission of 1888 traced its undoing and unhallowed end.

Chadwick in this same work declaimed against the "jobocracy of vestrydom"; many vestrymen were, he declared, "persons whose time is worthless, who are ignorant and wasteful or obscure persons who have some sinister interests to promote." Their paid officers, he said, were "under the necessity of having to work down to ignorance instead of up to scientific administrative principles." Slum-owners in some cases "got possession of the local boards of sanitary authorities," and as the Royal Commission on Housing subsequently reported "many of those whose duty it was to see that a better state of things was effected were those whose interest it was to keep things as they were."

Like some of his contemporaries, Chadwick regarded drainage as constituting a large, perhaps too large a part of practical sanitation. In 1885 he still clung lovingly to the "separate system" as he called it, epitomised in the phrase "the rainfall to the river and the sewage to the soil," and he mercilessly condemned the "combined system" adopted by that "vestral authority" as he stigmatised it, the Metropolitan Board of Works.

Basing himself on Farr's vital statistics, he maintained that "good sanitary measures under unity" might secure for the whole of the metropolis a death-rate not exceeding 11 per 1000, which then only obtained in a few favoured West-end districts. When Farr began his labours a death-rate of 25 per 1000 was not uncommon in London; in 1921 we have seen it at 12·5 per 1000.

In exemplification of his gospel of "Unity" Chadwick recalls that by the Poor-law Amendment Act, which he fathered, some 16,500 parishes were condensed into 660 unions, with great saving of unnecessary and wasteful expenditure and a marked increase of efficiency in administration. He proudly quotes the exclamation of Mr. Gladstone, "What would have become of the Poor-law Amendment Act, which is perhaps the greatest reform of this century, if it had been entrusted to the local authorities of that day!" To those who charged him with being "all for centralisation" he retorted, "I am on principle for extensive de-centralisation by well-arranged local consolidation, for superior self-government over that which now exists; a true representation of the best local intelligence under unity in the place of disunity and local ignorance."

He repudiated the soft impeachment of being a benevolent despot; if he aimed at centralisation as against the corrupt and inefficient local self-government he had encountered, it was, he said, "centralisation for the protection of liberty . . . ." If he condemned the *laissez faire* doctrine of those who claimed liberty for themselves and denied it to others it was because he held "Liberty is a right with a corresponding obligation to respect it. Liberty consists of the power of doing anything which does not hurt another."

Looking back from 1885 to his old battles of the 'forties and 'fifties, he reflects with sorrow rather than with anger or resentment on the "vote obtained under the combination of interests" which killed the General Board of Health, and sent him into a premature pensioned retirement. He recalls "the continued serious contraventions, which I was unable to withstand, of principles which were not understood," and how despite the "vexations and obstructions of half-knowledge," he had felt "constrained to go on" "for the sake of the gain to be obtained by other men after my time," and he added, "I do not regret."

His Friends and Co-workers.

If Chadwick had many enemies, whose names are mostly forgotten, he had also some devoted friends and coadjutors whose services to mankind are gratefully remembered. Let us recall some of these, who accepted the Chadwick school of thought and lent their invaluable support to the reforms he urged so insistently, often on deaf ears and shut imaginations. I have already alluded incidentally to some of them.

Dr. Southwood Smith (1788-1861) was a man after Chadwick's own heart. Born in 1788, at first a Unitarian minister teaching a universalist doctrine in Edinburgh, he later graduated M.D. at that University. From 1824 to 1839, physician to the London Fever Hospital, he spoke with authority on infectious diseases. If he were open to Simon's charge of "immensely under-rating the independent importance of morbid contagia," he displayed "a perfectly proper zeal against filth." He wrote and spoke with equal felicity, was an excellent anatomist, and I have already referred to his services to his master Bentham both before and after the latter's demise. He was the author of "The Philosophy of Health" and "Illustrations of the Divine Government," and contributed much of the distinctively medical portions of Chadwick's reports.

Dr. William Farr was born in 1807 and died in 1883. It is not without interest to note that the combined ages of Farr, Southwood Smith, and Chadwick spanned nearly two and a half centuries. Farr was described by those who knew him as "a man with the liveliest intelligence, with a mind revelling in generalisation, and a master of methods by which arithmetic is made argumentative." He made

Descartes' "Discours de la Méthode" his model. He recognised the limitations as well as the virtues of statistics, and would not have disputed the epigram that while "figures cannot lie, liars sometimes figure." He was the first to essay lectures on hygiene, was a man of large and liberal views, a glutton for work, of great personal charm, and of genial disposition.

Dr. Kay, afterwards Sir James Kay-Shuttleworth (1804-1877), wrote on the moral and physical condition of the working classes, studied typhus in Edinburgh and cholera in Manchester and helped to develop the system of national education. Kay, Southwood Smith, and Neil Arnott were the first medical men to be enlisted by Chadwick into the national service of public health. Kay-Shuttleworth was a great Liberal and, shall I blush to say it, a great Free Trader ?

Yet another co-worker and contemporary of those early Victorian days stands out pre-eminently as a sanitary reformer of the Chadwick type ; one whose heroic ministrations initiated military hygiene, and brought to the succour of the sick and wounded an informed gentleness and a humane efficiency which have placed the name of Florence Nightingale second to none among the venerated of her sex. It was Chadwick who assisted and encouraged her in drawing the moral of the Crimean muddling and in applying sanitary science to the army alike in peace and war. It was he who urged her to enlist the support of Kinglake and helped to popularise her "Notes on Nursing" with her plea for household hygiene and for "ample ramparts of fresh air" against zymotic diseases. It was Chadwick, too, who counselled her to continue her labours after the death of Sidney Herbert—her "Master" as she called him. With John Stuart Mill and Chadwick she coöperated in Poor-law and sanitary reform, and when the former died of fever at Avignon in 1873 she reproached Chadwick for not having had regard to the sanitary environment of their mutual friend.

Another personality of true nobility, not indeed a medical man, but a mighty social reformer ever to be held in reverence and esteem, was linked with Chadwick and Southwood Smith, and less closely with the others I have named, in the work of the General Board of Health from 1848 to 1855—I mean the seventh Earl of Shaftesbury. That lofty and independent embodiment of *noblesse oblige* successively and not unsuccessfully laboured to improve our asylums, our factories, our slums, our ragged schools, and common lodging-houses. He worked as ever in the Great Taskmaster's eye, an evangelist indeed, and "the impersonation of the philanthropic spirit of the nineteenth century."

In Parliament Lord John Russell was for years Chadwick's champion and supporter, while sometimes a little perturbed by the sanitary reformer's disregard of so-called local authorities. Russell declared that the Poor-law Amendment Act had saved the country from great social evils, if not from social revolution, and Gladstone even spoke of it as "the greatest reform of the century." On another occasion Lord John Russell asserted that "there was no one to whose zeal and assiduity the country is more indebted than to Mr. Chadwick." It was Prince Albert who obtained for him a C.B. in 1848, but he did not receive the accolade until he was 89.

His Vindication.

I have attempted, as requested, though very imperfectly, to sketch "the life and doctrine of Sir Edwin Chadwick." Whatever the verdict of history may eventually be, he stands for solid achievement in the story of sanitary and social reform. Much that was at the time ridiculed as the vapouring of a visionary has become the veriest commonplace of daily sanitary administration. "The stone which the builders refused has become the headstone of the corner." By instinct a democrat and a devotee of reform, his ruthless pursuit of his "sanitary idea" arrayed against him the interests who shouted him down as an "autocrat." Yet he and his school of thought taught nineteenth-century England a very salutary lesson.

They did not seek the causes of pestilence in visitations of an offended Deity, nor in convulsions of Nature ; nor did they set much store on epidemic constitutions of the air, or obscure telluric disturbances. They believed that they found in external physical conditions, largely removable and mostly the product of ignorance or neglect, the proximate antecedents of certain infections called zymotic. These were the nemesis of sanitary shortcomings, the evil fruitage of transgression of hygienic law, and in a sense, therefore, the penalty of moral misdoing. They looked to personal and civic cleanliness, ample supplies of pure air and water and wholesome food, decent dwellings, adequate exercise, reasonable wages and hours of labour and leisure, and the prompt removal of filth and effete material as important factors of national and individual health, and as specially potent against the invasion of pestilence which aforetime walked in darkness, but whose causation was now made manifest by the dry light of science. Further, they believed in the common origin, in filthy conditions, of many so-called specific diseases ; they believed in their generation *de novo* by such antecedents, as well as by their propagation through infection. They believed in the mutability of specific diseases, under the influence of favourable or unfavourable soil, holding that the soil must be studied no less than the seed, and that even though certain vegetable or animal particles or ferments stood in some sort of causal relationship to them, the predisposing causes were not less important, and indeed could hardly be overrated. In practical application they sought to influence for good the environment of mankind, making the battle-ground with disease *without* rather than *within* the uninfected body, setting great store on the natural vigour of the healthy body itself as the best security against its successful invasion by inimical agencies.

This, then, was the wholesome doctrine inculcated by Chadwick and his school. "Man's mere opinions must ever be liable to error. By the motives which sway his heart can he alone be judged" ; and I venture to assert that any impartial student of the life work of Edwin Chadwick will rise from his task with the conviction that the motives which swayed his heart were the disinterested love of his fellow man and the devotion of the highest gifts to the amelioration of his lot and the betterment of his life.

WORMS IN A HERNIAL SAC.

IN a recent issue of *El Siglo Medico*, a medical journal published in Madrid, Dr. Carrasco, chief of the civil hospital at Bilbao, places on record a case which occurred in his hospital practice 25 years ago, and which has remained unique in his experience. He states that on Feb. 20th, 1899, a woman attended the hospital with a child of 2 years old who had a distended tumour in the scrotal region. The tumour was painful and as large as an orange, somewhat fixed, and dull on percussion. There was no fluctuation which might have indicated hydrocele. Pain had persisted for eight days and, according to the mother's statement, the hernia was congenital. The abdomen was tympanitic and the child suffered from vomiting of fæcal character and constipation. Believing this to be a clear case of strangulated hernia, Dr. Carrasco was much surprised to find on incision a sac whose walls were as transparent as glass, and distended to the point of rupture by a shapeless mass of living ascarid worms. The worms were twisting and writhing as if trying to break the walls of their prison. He attempted to empty the sac by gentle pressure but to no purpose ; the ascarids formed a tangled bundle, and the herniated mass was so large that even after incision of the constructing ring he was not able to reduce the condition. As something had to be done, the intestine was opened and more than 60 worms were withdrawn, several of which measured more than 25 cm. in length. While the intestinal wound was being sutured several more worms appeared in the diverticulum as if the intestine were a veritable breeding-ground. He removed the diverticulum and the child left the hospital when the wound was healed, but no subsequent history has been available. Dr. Carrasco states that he cannot find in medical literature any account of a similar condition.

The classical description of a varicocele (presumably also in Spanish medical schools) is that, on palpation, it "has the feel of a bag of worms." A bag of worms is hardly an object met with—much less palpated—in everyday practice, and in a case like the above, where such a bag actually came under the doctor's fingers, no suggestion was made that it had "the feel of a varicocele."

THE THERAPEUTICS OF PAIN.

WITH this title Prof. James J. Walsh, of New York, has written a paper[1] which is a study of the means taken to relieve pain from the earliest days of primitive medicine to the present time. His main thesis is that there has been no change in the underlying principle, although its uniformity has not been recognised, and the different cloaks under which it has been concealed have been regarded as fundamentally distinct from age to age. Suggestion, Prof. Walsh argues, has relieved more pain and cured more disability than any other known remedy, and whether it be conveyed by the metallic tractors of Dr. Elijah Perkins or by the phrases of Mr. Coué, the result is the same, provided the patient's mind is in a properly receptive state. The history of the famous St. John Long liniment a century ago is typical of certain remedies in every age. This liniment cured even tuberculosis and was held to be so marvellous in its action that the British Government of the day paid an enormous sum for its secret. When this was divulged and the liniment proved to be only an ordinary turpentine liniment made with the yolk of egg instead of with oil, it ceased to be so effective in the relief of pain. So great, indeed, was the disappointment over the publication of the formula of this liniment, that St. Long John was accused of concealing the real secret and selling a misleading formula. In his review of the history of the Perkins' metallic tractors, with which Oliver Wendell Holmes was treated, Prof. Walsh suggests that the English are peculiarly amenable to suggestion. He writes of Perkinism: "Dr. Perkins's son carried it over to England where there is always a fertile field for such novelties in therapeutics and where there are always a large number of educated people waiting to be cured by something that has just been discovered and has cured nobody before them, and was manifestly, in some way or another, intended for their special benefit."

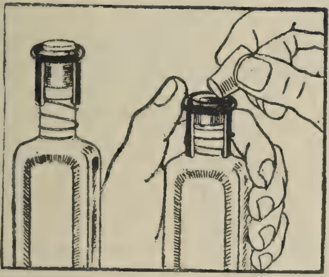
---

[1] International Clinics. Philadelphia: J. B. Lippincott Co. 1923. Vol. III. Thirty-second Series.

In the matter of quack remedies we are not prepared to argue that there is an excess of exports over imports as between this country and the U.S.A., but it is doubtful if Prof. Walsh is correct in associating, as he does, credulity with education. He is, however, assuredly correct in his statement that the well-known fallacy, *post hoc ergo propter hoc*, has always been the source of an immense amount of knowledge in medicine that had no foundation in reality. In so saying, he is but paraphrasing the familiar words of Josh Billings, "it would be much better not to know so much that you know so many things that ain't so."

THE POISON BOTTLE.

WITH the object of calling attention to the fact that a bottle contains poison, Messrs. Furness and Richardson, 61, Tweedy-road, Bromley, Kent, have placed upon the market an ingenious device (vide illustration) which makes it impossible to withdraw a cork until a semi-cylindrical guard, terminating in a ring, horizontal to, and at the level of the cork, is pressed down so as to permit the fingers taking hold of the cork. The guard, which can be made in various standard sizes and of various suitable materials, is kept in position by a spring placed around the neck of the bottle. The name of devices for preventing the careless use of bottles containing poison is legion, but it would seem impossible entirely to guard against human error in this connexion; any device, however, which compels individual attention is to be commended. The weak point in the present device is that it is not a fixture. Laziness might prompt its removal. The retail price of the article is 6*d*.



THE OLD CAIRO MEDICAL MISSION HOSPITAL.

SINCE the appearance of the last biennial report of the hospital many changes have taken place in Egyptian political life, notably the elevation of Egypt to the status of an independent kingdom, but as the principal medical officer of the hospital, Dr. F. O. Lasbrey, states in a preface to the report for the years 1922-23 the Egyptians themselves are not essentially changed and the hospital is still as popular as it was in the old days. It provides the accommodation of some 180 beds, 150 in the men's hospital and 53 in the women's hospital, while there are open-air pavilions which can accommodate from 600 to 800 cases for resident patients suffering from ankylostomiasis or bilharziasis. These cases lie on mats instead of beds, as most of the beds are devoted to surgical cases. While the numbers attending the hospitals during the years 1922-23 did not quite equal those of the record year 1920, they are not far short of that figure and the numbers of general surgical in-patients have kept up steadily. In the section for the treatment of ankylostomiasis 10,975 cases were treated during the two past years, and it is interesting to note that in addition to the above about 80 per cent. of the regular surgical in-patients take this course of treatment during their stay in hospital. These numbers show a considerable reduction on those of the last report. One reason for that is that the Government is now undertaking widespread treatment of this disease throughout the country. The routine treatment is still chenopodium oil, which must be fresh to be effective. In the section devoted to bilharziasis 2053 invalids were treated during the two years. The treatment adopted is that of injections of antimony tartrate, and the sodium salt is now used in preference to the potassium as the former was found to be less depressing. The latest figures seem to prove that, in practice, in every case the worm and eggs will be killed if only the patient will continue till the end of the course, but unfortunately a certain proportion find such benefit after taking two-thirds of the course that they do not wait to complete the requisite number of injections. In general surgical work the favourite anæsthetic for all suitable cases is stovaine given intrathecally, and over 3000 operations have been performed with this anæsthetic during the last few years with most satisfactory results. Egyptian splenomegaly is still treated by splenectomy, and the recent case mortality has been kept to the satisfactorily low percentage of 15·7. The ophthalmic section has shown the most marked progress during the last two years; nearly 25 per cent. of the total number of out-patients attending the hospital have been eye cases, the prevailing diseases being trachoma and trichiasis, for which, in the period under review, over 3000 operations were done. Considerable success attended the work carried on by means of tent hospitals during the winter months, two separate camp dispensaries being established.

The Medical Mission which is conducted at Menouf under Dr. A. R. Hargreaves, principal medical officer, has suffered some diminution in the extent of its work during the past two years, due partly to the increasing numbers of doctors practising in the country towns and in the villages, and partly to the increased facilities for travelling to Cairo. On the other hand, the lessened wealth of the peasants has had an adverse effect on the mission work. The hospital at Menouf has accommodation for 40 in-patients and there are out-patient dispensaries at Ashmoon, Bei el Arab, and Shubra Zanza.

MACKIE'S CHARCOAL BISCUITS.

CHARCOAL biscuits may often prove a useful adjunct to the treatment of certain well-known affections of the stomach and intestines. We have received from Messrs. J. W. Mackie and Sons, Ltd., purveyors to His Majesty the King, a sample of their biscuits, which they state are made from the purest vegetable charcoal. These biscuits are entirely free from grit and are just sufficiently sweet to make them pleasant to the taste.

MOTOR-CARS FOR DISABLED PERSONS.

IN collaboration with Captain Richard Twelvetrees, Messrs. G. W. K., Ltd., of Maidenhead, have recently introduced one of their standard light car models converted to hand control. We are informed that after extended tests both in traffic and under ordinary touring conditions, it is found that the car can be handled with comfort and safety; apart from the alterations to the controls the chassis mechanism is standard. The form of friction drive which has been used on this make of car for many years is said to lend itself well to the needs of the disabled driver, for there is no danger of missing the gears. The alteration to the mechanism consists in pivotting the steering column at its lower end, so that to get a free engine the driver has only to pull the steering wheel slightly towards him. A continuation of the movement applies one of the brakes, and it is said that at a speed of 48 miles an hour the car can be brought to a standstill within a distance of 40 yards by the use of the steering wheel brake alone. A very slight pressure on the wheel releases the drive sufficiently to enable the driver to alter the gear ratio by the usual form of side lever and a second brake is operated by a side lever. Though normally situated at the right-hand side of the driver, the two levers can be located at the left in cases of right arm disablement. The manufacturers are prepared to convert a standard model to suit individual clients with various forms of disablement without extra charge.

The innovation is said to bring motoring within the reach of those who suffer from amputation of one or both legs. We agree that it is desirable that as far as possible disabled persons should be helped to lead a normal social life, and that adjustments of mechanical contrivances to this end are of great value. There is, however, another side to the question, that of the public safety. In view of the fact that a licence to drive does not necessarily imply ability to do so, it would be wise of any disabled man to submit himself to some recognised test and acquire a certificate of competency before taking the road. If this precaution has been taken any accident which may occur will not be regarded as a reflection on his power of controlling the machine.

SMALL-POX INOCULATION IN 1760.

Although it is known, in a general way, that inoculation for small-pox was performed in the eighteenth century, it is not often that contemporary mention of the practice is to be found, and therefore considerable interest attaches to a couple of old family letters, dated 1760 and 1763, in the possession of Arthur Bowes Elliott, F.R.C.S., of Abergele, in which reference is made to this method of preventing the ravages of the disease. The Bowes family were for generations doctors in Richmond, Yorks, and neighbourhood, and the inoculation described in the following letter was doubtless performed on Mr. Bowes's apprentice for the sake of example :—

> " Bedale, Feb. 25th, 1760.
>
> " Now at last I have written to you, as I know you will be very inquisitive to know how Affairs go about our Inoculation, you must know we are to begin to prepare tomorrow for the first Time in Earnest, and then we are to have a Water* podish twice a day, and more Puding than any of us wish for, but however I am resolved to go thro' : with it, tho' it be at the Expe'ce of many a Hungry Belly.
>
> Mr. Bowes's Apprentice and his Sister were Inoculated on Monday the 13th Inst., and have just heard the Small pox were coming out yesterday, but have not heard anything to day but will let you know on Saturday. I assure could wish you for my Nurse, tho : I almost despair of that Favour, however I know you'll wish me well, and that will contribute a good Deal to my Recovery. I am, dear Coz., yours to command
>
> Willm. Prest."

Letters from a young lady in Richmond, Yorks, have frequent references to the small-pox being all round her in 1762–1763. On Oct. 30th, 1763, speaking of a Dance there, she says :—

> " Mrs. M. and Mrs. S——, has never had the Small Pox and some of the Company had them in ye Family, so that I fancy the Ladies was in parties. Inoculation has had great Success, and Miss W——r had no appearance so that it shows all Constitutions are not liable to take them." . . .

Dr. Kenneth Rogers, to whom we are indebted for the letters, adds : " The frequent mention of the small-pox (always used correctly as the plural of Pock), as an *inevitable* disease—e.g., such a reference as ' I wish Mrs. So-and-So's little folks were through them,' is of interest in these days when the *anti*-vaccinators are loud in the land ! "

EATING WITHOUT FEARS.

Cookery books are many and of varying excellence, and it is always a pleasure to us to know that one of the best was written by a member of our own calling—namely, the " Cook's Oracle," by Dr. William Kitchiner. The philosophy of dining has been set forth by many great writers, notably George Meredith and Thackeray, the former of whom wrote : " If it be a distinct point of wisdom to hug the hour that is, then does dinner amount to a highly intellectual invitation to man, for it furnishes the occasion ; and Britons are the wisest of their race, for more than all others they take advantage of it. In this Nature is undoubtedly our guide, seeing that he who, while feasting his body, allows to his soul a thought for the morrow, is in his digestion curst, and becomes a house of evil humours." As for Thackeray, it is unnecessary to do more than mention his " Memorials of Gormandizing," and the inimitable Fraser paper entitled " Barmecide Banquets with Joseph Bregion and Anne Miller." Mr. Scotson-Clark has recently published just such a book[1] as would have delighted either of the above-mentioned authors. We do not agree with him on one or two points—e.g., it is a mistake to say that cream is very fattening (p. 27) and to cook kippers by warming them through in a frying-pan with a little water is anathema (p. 45). Kippers should always be either grilled, or best of all done in a Dutch oven, a cookery armament which we are glad to see Mr. Scotson-Clark praises. With these exceptions the book is admirable, though we contend that larks are much too fascinating and too valuable to the agriculturist to be eaten. Mr. Scotson-Clark is not afraid of garlic, which too many modern housekeepers shy at ; also he lays stress upon the fact that curry to be good should always be made from fresh meat. His recipes for spaghetti and risotto are perfect, and also his directions for cooking poultry. Chapon au Mais is a dish known to few and an excellent one at that, and we will add one of the same kind —namely, a medium-sized tender fowl, stuffed with flavoured rice, i.e., rice to which pepper, salt, butter, and a trace of garlic has been added. This is to be placed inside an ordinary yellow melon from which the seedy interior has been removed and some veal stock added. The lid of the melon is replaced and tied on with string and the whole is then baked in a slow oven for one and a half hours. On curries and soups Mr. Scotson-Clark is equally good. We can only add that to read his book makes the reader hungry, and hunger connotes health.

ARTIFICIAL RESPIRATION.

Captain G. R. G. Fisher, who is an instructor in first-aid in Omaha, Nebraska, and has also done similar first-aid work in this country, has written a little manual[1] which conveys some useful instruction in letterpress and pictures. It is designed especially for those who are employed in industrial or mining works, and for policemen and firemen. The style of writing is likely to make a greater appeal to American than to British readers.

DIABETES TREATMENT CHARTS.

We have received from Messrs. H. K. Lewis and Co., Ltd. (28, Gower-place, London, W.C. 1), a specimen copy of a new chart designed by Dr. O. Leyton for use in the treatment of diabetes. The chart is arranged for recording in graphic form the dosage of insulin, the constituents of the diet in grammes and calories, and the progress of the case as shown by the body-weight and the percentage of sugar in the blood and urine. The price of the charts is 25 for 2*s.*, or 100 for 6*s.* 9*d.*

EYESIGHT IN INDUSTRY.

A study,[2] emanating from the office of the League of Nations, has for its object to encourage further research into the problems of industrial lighting, to disseminate knowledge of the principles involved, and to enlist the coöperation of employers, and workmen's organisations in putting these principles into practice. After defining units of illumination and describing different methods of photometry, the pamphlet classifies and compares the different sources of artificial light. With regard to their effect on the eyes of the worker, the main stress is laid not in the kind of light, but on its position on globes and reflectors, and on the relative amount of illumination necessary for different occupations. The physiology of vision is touched on so far as it is concerned with visual acuity, light and dark adaptation, and the various reflexes in which different parts of the visual apparatus are concerned. A correct summary of the present state of our knowledge on the effects of the invisible rays on different parts of the eye is given ; there is a useful chapter on industrial accidents arising from defective lighting and another on prevention of eyestrain and protection of the eyes by glasses. It will be seen that the brochure covers much ground in a short space. A useful bibliography is appended. The only slip we have noticed is the curious repetition of the word " pupils " for " eye-lids " in three separate places.

VASECTOMY INSTEAD OF CASTRATION IN LIVE-STOCK.

To the Editor of The Lancet.

Sir,—In a recent issue of the *Overseas Mail* reference is made to an experiment about to be undertaken by Dr. Serge Voronoff, whereby he hopes to evolve a permanent new breed of heavily clad animals. This refers to an experiment on sheep to provide more wool. Now, as a matter of fact, I have been urging vasectomy in Cape Colony for this purpose for the last 14 years (*Agricultural Journal, Cape*, August, 1909), but without much progress. In October last Mr. du Toit, Director of Veterinary Education and Research, Pretoria, kindly undertook an experiment with vasectomy, treating six lambs and setting aside controls. The other day he sent me a report in which he says : " It is too early yet to give a final verdict on the result of the small experiment conducted by us, but it would appear as if the method is of real practical value to the sheep farmer." The same department informs me that the procedure is easily carried out at the rate of 30–40 per hour. Veterinary surgeons admit the theory but demur at the difficulty of the process, which must, however, be faced if 16*s.* extra wool and 40*s.* more beef is produced per unit in flocks and herds. As regards the sexual impulse, if vasectomy is performed shortly after birth the sexual arc is broken, the centre atrophies, and the animal is quiet and manageable. I understand that at one time hearse horses in London were so treated and proved useful animals. We may suppose that the germ function being in abeyance, the Sertoli cells receive more nutriment and thus create more wool and vitality in the animal.

I am, Sir, yours faithfully,
W. Robertson.

Mossel Bay, South Africa, Feb. 19th, 1924.

---

* ? Possibly a corruption of potage. From the context it would appear to be some " slop " diet.

Some Questions

CONCERNING THE INFLUENCE OF TROPICAL CLIMATE ON MAN.

An Advanced Lecture in Hygiene delivered under the Auspices of the University of London

BY DR. C. EIJKMAN,
PROFESSOR OF HYGIENE AND MICROBIOLOGY, UNIVERSITY OF UTRECHT.

IT has been complained, and not without justice, that between the tropics the fertile regions are unhealthy and the healthy ones sterile. It is, indeed, the high temperature and the moisture combined that, especially along the coasts, not only cause the luxuriant growth of plants, but also give rise to a number of originators of disease, and, moreover, exercise directly an exhausting and enervating influence on man. In comparison with former times, however, a considerable improvement is noticeable in the general sanitary condition of tropical countries, though it is not always possible to express it in figures. Their proverbial unhealthiness for the white man has lost much of its terror, since it is no longer for the greater part the scum of European society from which the immigrants are recruited, and since the conditions of living there have so much improved, with better medical aid and sanitary measures more amply provided for. No wonder that the pessimistic criticisms of yore have already undergone a considerable change and are even in a fair way to be replaced by rather too optimistic views.

Malaria, yellow fever, cholera, dysentery, plague, beri-beri, ankylostomiasis, those scourges of the tropics, are all, it is argued, avoidable diseases—avoidable, because science has discovered their causes and thus provides the means of combating them with success. Well, then, take them away, those diseases with their causes, and there will remain the healthy inhabitant of the tropics, the "permanent summerman" (Stokvis).

A great deal has been attained in this respect, but, on the other hand, it must be acknowledged that in practice many difficulties have cropped up, some of them quite unforeseen and some of them as yet insurmountable, and even if one succeeded in closing Pandora's box entirely all would not be gained. Health is not a mere negation of illness, it also implies something positive. The full use and control of the mental and physical functions, a vigorous constitution, a considerable amount of bodily well-being—those characterise the healthy man. Much of this the sojourner in the tropics lacks, though he may be exempt from illness. This especially applies to the white man, and the consolation that he is a "permanent summerman" cannot make up for this deficiency.

What at once strikes every one who arrives in tropical regions for the first time is the pale complexion of nearly all the whites. It is such an ordinary phenomenon that people who have resided in tropical climates for some time hardly notice it. To them, however, the newcomer with his fresh colour is a striking appearance. It is not long, however, before the blood has disappeared—usually within a year—to be replaced by a pale complexion, which is often yellowish, owing to pigmentation. This change was generally considered a sign of the development of the so-called *tropical anæmia*. In the absence of duly equipped institutions for experimental research in the tropics, people formerly—and occasionally even now—held this more or less a priori view of the physical changes that take place in the inhabitant of cooler regions. His former surroundings, it was argued, and his consequent natural disposition and organisation rendered his metabolism, heat production, and physical powers vigorous, the action of his skin, however, being often comparatively slight. His transference to the hothouse atmosphere of the tropics must work a complete change in that organisation in those functions. In other words, his body must undergo a process of acclimatisation if he is to adapt himself in the long run to surroundings so entirely different. When, to find an outlet for the body heat, his skin reaction has increased considerably and the sweat secretion has augmented to superfluity, he will gradually adjust himself to a limited production of heat. Not only is muscular action, the source both of mechanical force and of heat, avoided as much as possible during the hottest part of the day, not only does the metabolism become less intense and the need of food less urgent through the absence of the stimulus of the cold, not only does the breathing become less deep and conduct less oxygen to the blood, owing also to the rarity and humidity of the hot air, but the composition of the blood, too, is modified accordingly; it becomes thinner and paler. Or, as a French author (Saint-Vel) has it: "L'européen ne tarde pas à offrir le léger degré d'anémie qui semble physiologique tant il répond aux conditions de la santé sous ces latitudes. Il n'a plus besoin d'un sang aussi riche et d'une respiration aussi active; il n'a plus à produire une aussi grande somme de calorique pour résister à un climat rigoureux; il n'a qu'à s'accommoder au nouveau climat et à s'y laisser vivre en quelque sorte."

Such was the generally accepted meaning of the supposed anæmia and the lessened vital power of the white sojourner in the tropics. He is enabled to endure the heat better, not by active resistance, but by a passive adaptation to it. Thus, according to the line of thought set forth here, the acclimatised white is a weakling, doomed to lead a languishing existence, an inferior person whose health is in a state of unstable equilibrium amid the many noxious influences to which he is exposed in the tropics. As a French naval doctor (Laure) expressed himself already 60 years ago: "En arrivant à Cayenne, on croirait tomber dans la cour d'un hospice." What a contrast with the native! According to the accepted notion, his pigmented skin, in its power to radiate heat, surpasses the white's so much that neither a frequently excessive, but at the same time debilitating secretion of sweat, nor a considerable diminution of the heat-producing vital functions is required to preserve the equilibrium of heat. So that in contradistinction to the white, who in the middle of the day seeks rest and shelter from the sun, he can remain in full activity. With him, therefore, there is no question of anæmia, of considerably diminished vital energy, of enhanced liability to morbific influences.

So much for the theory. It must be acknowledged that, since in this connexion physiological deduction has given way to experimental research, our notions concerning the influence of the heat on the constitution of the sojourner in the tropics has had to be rather considerably modified. In the Dutch East Indies this research has become possible through the establishment, more than 30 years ago, of the medical laboratory at Weltevreden (a suburb of Batavia), of which I had the honour to be the first principal.

It will be clear, after what I have said, what are the problems we have proposed to ourselves and selected for research. I flatter myself that the results of these investigations are still of sufficient interest to be stated here, the more so because in my perusal of the English literature on the subject it has appeared to me that they have remained all but unnoticed in this country.

TROPICAL ANÆMIA.

Is the pale complexion of the white sojourner in the tropics a symptom of anæmia? Almost simultaneously with and independently of us, two other investigators put this question to themselves—viz., the Frenchman, Marestang, and the Dutchman, Van der Scheer. A count was made of the red blood cells per volume-unit of the blood, as also a colorimetric determination of the hæmoglobin content. Both were found conformably by the three experimenters to lie within the same limits for the white sojourner as in the case of the newcomer and of the native. It stands to reason that for these experiments persons were chosen who might be considered healthy, though the first group looked pale. Later on these investigations were extended in the Weltevreden Laboratory to the specific weight and the water-content of the blood as well as of the plasma, again with the result that no differences could be detected. The same may be said with regard to the osmotic tension. Nor was there any evidence of micro- and poikilo-cytosis, as will occur in anæmic conditions. So the above question, whether the pale complexion is a symptom of anæmia, must be answered in the negative.

Besides, we had an opportunity to make observations in a couple of cases on the regeneration of the blood after acute traumatic hæmorrhage. The first case concerned a Dutch sergeant, 32 years old, who had been in the Indies for three years and a half, and who, in an attempt at suicide with a razor, had inflicted a deep wound on the front of his neck, cutting one of the thyroid arteries. I did not get an opportunity of examining him till a fortnight afterwards. The number of red blood cells amounted then only to 3,620,000 per c.mm., the hæmoglobin being 72 per cent. An examination repeated every ten days showed that the first had returned to the normal 34 days after the loss of blood and the other 44 days after it.

The second case was that of a Dutch soldier, 25 years old, four months in the Indies, who on going outside one morning before sunrise happened to fall on a splinter of glass, which penetrated deep into the right side of his neck, just above the collar-bone. About an hour after the accident he was found lying unconscious in a pool of blood. I had the opportunity of examining him on the next day. It appeared that the right truncus thyreo-cervicalis (a. clavicular) had been severed. The red blood cells amounted to 3,162,000, and the hæmoglobin was 60 per cent. In determining the relative volume of the aggregated blood cells it was also found that about 40 per cent. of the blood must have been lost. Notwithstanding this he looked rather ruddy, another proof how one may be mistaken in judging the condition of the blood by appearance only. The specific weight of the blood was 1·046 (normal 1·058), that of the blood-plasma 1·027 (normal 1·029). The weekly repeated examination showed that the loss had been completely restored after seven weeks.

In comparing these results with the statements in the literature on the subject, one gets the impression that the regeneration of the blood after a great loss is not less complete in healthy white men in the tropics, nor markedly slower than in the temperate climate. All things considered, *there exists no purely physiological anæmia of hot countries.*

It might be thought that the pale complexion was due to a diminution of the total mass of the blood (oligæmia). Methods, such as those of Zuntz, Haldane, &c., to determine this mass in vivo were not yet known at that time, and in that direction, therefore, the investigation might be extended. However, I do not expect much from this, partly because these methods are not yet very exact, partly because neither clinical nor post-mortem observations indicate that the vascular system has suffered in this way. Notwithstanding the pale complexion, the pulse is fairly well-filled, the blood pressure not lowered, and the internal organs do not give the impression of a paucity of blood. It is even the current impression among tropical practitioners that the abdominal organs are overfilled with blood, seeing the pronounced liability to diseases of these parts, often attended with bloody excretions. In this connexion Van der Scheer calls attention to the experiments of Dastre and Morat which have brought to light an antagonism between the blood-vessels of the bowels on the one hand and those of the muscles and skin on the other. This would seem to account, not only for the paleness of the sojourner in the tropics, but also for his sensation of weariness and disinclination to physical exertion. To me all this seems too hypothetical, ingenious though it may be, and I think the explanation is to be sought in another direction, although it is rather an analogy than an explanation that I offer. In the cooler regions it is only the regularly uncovered skin, directly exposed to the influences of the weather, that is generally distinguished by richness of blood; this ruddiness is a local phenomenon. The covered skin, on the contrary, is usually pale and—this is the analogy referred to—may be said to be in an artificially tropical climate with a temperature amounting as a rule to more than 30° C. The same parts of the skin that are usually red in the cool climate, with its strong variations of temperature, in course of time assume a pale colour when they are almost continually in warm surroundings. Nor does the skin of the face form an exception in this respect. We need only call to mind the pale complexion characteristic of people who lead a sedentary life. In these cases, too, as Sahli and Oppenheim have demonstrated beyond dispute, this need not at all be an indication of general lack of blood.

Finally, I wish to point out that in the Malay race, too, examples may be found of fresh complexion, though tempered by the skin pigment. I saw this not only in Holland but also in the mountains in Java and Sumatra, and I remember very well—I was then so many years younger—that it made the young native girls there look exceedingly pretty. In the hot littorals, on the contrary, the skin of the native's face is also anæmic, although nobody will consider this as a symptom of general anæmia, as has been done in the case of the white.

Metabolism and Heat Production.

In tropical countries the aborigines live chiefly on vegetable food, which is ordinarily rich in carbohydrates, comparatively poor, however, in proteins, and often also in fat. In my time rather extensive investigations were made in the Weltevreden Laboratory into the food both of Europeans and Malayans. Each of the subjects of experiment furnished us for four days successively with a sample of his daily ration for analysis, and the urine and fæces were also examined.

The following is a summary of the results :—

—	Body-weight.	Protein.	Fat.	Carbo-hydrates.	Alcohol.	N. in urine.	Calories.
	kg.	g.	g.	g.	g.	g.	
8 Europeans	65·4	99·6 (88·6)	83·8 (94·4)	264·2 (97·0)	28·5	13·45	2471
5 Malay students ..	49·6	73·3 (76·1)	30·2 (83·0)	471·9 (97·7)	—	8·74	2512
4 ,, servants ..	47·5	67·7	21·8	484·6	—	8·45	2465

N.B.—The figures in parentheses indicate the percentage of utilisation.

The difference between the two races as regards the protein and fat content of the food is obvious. With the Europeans only 25 per cent. of the protein was derived from vegetable food, with the Malayan 70–80 per cent. I am not so sure that this is due to instinctive compliance with the requirements of the climate, for we see the same thing in the Japanese, who is not really an inhabitant of the tropics. Owing to the relative cost of animal food, economic causes may be at work here similar to those which elsewhere compel the poor to become vegetarians. Indeed, on festive occasions the Malayan is by no means averse from animal foods and from fat (cocos oil).

From Rubner's standpoint, that the organic foodstuffs can interchange in isodynamic proportion, it is to some extent immaterial from which of them the body derives its necessary energy. On the other hand, however, we should take into account the specific dynamic action of protein, which manifests itself by an increased heat production above the basal level. Moreover, according to Chauveau, in the performance of muscular work the metabolism of fat causes a greater part of the liberated energy to be converted into heat than the metabolism of carbohydrates—a view which tallies better with the experience that a diet rich in fat is more appreciated in cold than in warm countries.

A peculiar view, assigning great value to the source of the fat, has been put forward by Körfer. He even proposes to distinguish the three zones, into which climatology divides the surface of our planets, as train-oil zone, suet zone, and vegetable-fat zone.

Finally, some medical men, obsessed by the dogma that a substantial food must needs be rich in protein and fat, have advocated its wholesomeness for the tropics as well, overlooking the fact that whole nations and working classes can develop well and live healthy lives on a minimal consumption of animal food. They would force upon the indigenes an unusual diet, prepared after European recipes, specially with a view to the prevention of beri-beri. But both in the Dutch East Indies and in Japan these efforts to effect a radical change in the diet of soldiers and sailors have failed; there is no forcing the taste after all.

Returning to our figures after this digression, we want in the first place to point out that the utilisation of the various foodstuffs for both groups of subjects was very satisfactory. The caloric value of the average daily ration amounts for both groups, in round numbers, to 2500 calories. Our European subjects (hospital and laboratory doctors, men nurses) fall under Rubner's first category of labour (light labour), for which he allows 2630 calories per 70 kg. of body-weight. Calculated for the same body-weight there results for our European subjects $\left(\frac{70\cdot0}{5\cdot46}\right)^{\frac{2}{3}} \times 2500 =$ 2590 calories. In the same manner the calculation gives for our Malayan subjects 3140 calories. They approach more nearly to Rubner's second category (medium labour), for which he allowed 3120 calories. So our findings for both categories accord pretty well with Rubner's and confirm what Voit, solely judging from information that had reached him about the food supply in hot climates, had already stated as his impression years ago, *the food requirement is, with about similar labour conditions, as great in hot as in temperate climates.*

Nevertheless, since muscular work and the consumption of food influence metabolism to an extent which cannot be estimated with sufficient accuracy, it was advisable to exclude them. As is known, the usual method for this is the determination of the respiratory gas exchange in the morning hours before breakfast in persons at complete rest. From the amount of oxygen consumption, taking into account also the respiratory quotient, the basal metabolism is calculated—i.e., the number of calories produced per hour per square metre of body surface. We found, both for the white and the coloured race, an average of about 40 calories, which corresponds entirely with the figures given by other investigators for mean Europe and for North America. On the other hand, Ozorio de Almeida in Rio de Janeiro gives considerably lower figures for both the white and coloured races. In support of mine I may add that my own basal metabolism, examined in winter in Holland in a room temperature of 9° C., appeared to be the same as it had been two years before in a temperature of 27·5° C. in Batavia. The opportunity of making such a control experiment on the same person will naturally remain exceptional, hence, after my return to Holland, I made comparative determinations of the basal metabolism in ten persons in summer- and in winter-time. Here, too, no essential differences could be noticed, though, with about the same clothing, the difference in room temperature was very considerable (16° C.).

I readily admit that when in Batavia I started the investigations described here, I had not quite expected these results, and I was inclined to share the view that the heat production would be lessened under the influence of the hot climate. Not that I believed in what I would call the "bellows theory," the conception that the combustion in the body might be compared to that of an open fire, which burns the more fiercely the more air is conveyed to it. There is no doubt whatever that though in a cool environment more oxygen were to be introduced into the organism than in a hot one, the consumption of it need not therefore be increased. The living organism regulates this according to its requirements, and possesses an excellent compensating mechanism for the purpose. Besides, it should be borne in mind that, even in the coolest and driest atmosphere, before the air has reached the lung cells, it has already been heated within the air passages to body temperature and saturated with vapour. Nay, in ordinary, quiet respiration the inhaled air does not even stream into the lung cells, but reaches no farther than the air passages, whence the gas exchange with the lung cells is brought about by diffusion. So it is never the outside air as such that is directly concerned in the gas exchange in the lungs, but always warm and moist air—no matter in what climate or season.

What suggested to me the occurrence of a less vigorous metabolism in a hot environment was the experiments on animals made by the school of the famous physiologist Pflüger, who concluded that it is the stimulus exercised by the cold on the skin that automatically stimulates the heat production in the muscles, even without necessarily betraying itself by noticeable contractions (so-called still labour). A second consideration for me was the following: The calculation of the basal metabolism starts from the experimental datum that the heat production is proportional not to the weight but to the surface of the body. In this was seen a confirmation of an already old hypothesis, advanced first of all by Immermann and by Helmholtz, that in warm-blooded animals there is a close relation between the intensity of the metabolism and the development of the body surface—that is to say, that smaller individuals with their relatively larger surface lose more heat per kg. body-weight than larger ones, and must produce more accordingly. Assuming this explanation to be true, it would follow that the heat production regulates itself automatically after the heat loss. If this were so, one might expect a direct influence of climate and season on metabolism and heat production. However, it has appeared since, among other things from investigations by my countryman Buitendijk, that the relation between metabolism and body surface not only holds good for warm-blooded animals, but also for cold-blooded ones, so that the explanation just given can hardly be true.

Thus, rather contrary to expectation, we could not bring to light any real differences, as regards metabolism and heat production, either between a cool and a hot area, or between the white and the coloured race. However, our results only referred to the state of bodily rest, as also to light muscular work of the whites, and moderate work of their Malayans. Now, it seems a general experience that the white cannot in the long run keep on doing heavy muscular work in the tropics; he must leave it to the natives.

I had intended to extend my investigations of the metabolism in that direction, but had no opportunity, owing to my return to Holland. I was then able only to determine the respiratory gas exchange of a couple of white subjects during rather heavy labour and at room temperatures varying from 12° to 30° C. The investigation lasted from the month of March to the middle of July. My subjects, trained cyclists, were seated on a stationary bicycle arranged as an ergometer, so that by the pedalling motion a measurable and dosable resistance was overcome. The tempo of pedalling was given by a metronome and amounted to 130, the labour performed to

380 kg. a minute. The determinations of the gas exchange were made after 20 minutes' pedalling. At the conclusion the subjects, though not exhausted, felt tired, just as if they had taken a rather long bicycle ride. Now, in contrast with what had been found for the state of complete rest, it appeared that the temperature of the environment, as soon as a certain limit upward is surpassed, exerts a decided influence on the gas exchange. This limit in both subjects was reached at 21°–22° C. The average oxygen consumption above that limit increased for the one by 31 per cent., for the other by 48 per cent. The carbon dioxide production ran pretty well parallel with it, so that the respiratory quotient remained about the same. The respiration volume, too, increased, though in a less degree.

Consequently the labour is performed less economically, and this contributes to our getting so much sooner fatigued in the heat.

HEAT REGULATION.

As we have seen, there is, according to our findings, in a hot environment practically no question of an automatic limitation of the heat production—in other words, of a *chemical* heat regulation. Almost the only thing that has any effect in this respect is an adequate limitation of the muscular labour. For the rest, it is for our body to regulate the heat loss which is effected chiefly by the skin and the lungs, and that in such a way that it may be appropriately called *physical* heat regulation. The lungs hardly take part in this; they yield less heat to a warm, moist atmosphere than to a cold one, and one does not get the impression that during a man's labour in the heat the ventilation of the lungs increases in such a degree that there may be a question of compensation, as is so clearly seen in some animals—e.g., dogs. We may, therefore, confine ourselves to the heat-regulating function of the skin, and it is essential to examine whether the white is in this respect inferior to the coloured skin. In this connexion we shall have to consider the three ways in which the skin yields up the body heat—viz., radiation, convection, and perspiration.

The skin is protected by its pigment against the inflammatory action of the sunlight; at the same time, however, the coloured skin absorbs more heat than the white one, which reflects a greater part of the sun's rays. Of two identical thermometers the bulb was covered with a double layer of skin, with the difference that in the one white skin was over brown, and in the other just the reverse. Both thermometers were placed then in a closed humid space, irradiated equally by the sun. After some time the thermometer with the white skin outside had risen to 47·5° C., that with the brown outside to 50·1° C. A similar difference may be observed by merely touching the living skin, after the sun has for some time shone on it. On the other hand, it might be that the dark skin radiates the body warmth more easily. The much-quoted author Woodruff remarks in this connexion: "Black bodies radiate heat to cooler ones much faster than bright bodies do. Blond men can stand cold far better than the negro, who radiates so freely that he needs more clothing and warmer houses. The inability to radiate heat makes the white man suffer from overheating in the tropics, his temperature rising with that of the air."

This assumption of Woodruff's seems to me to be a physical heresy. The colour of an object has no influence on the emission of dark heat rays. Provided the surface be the same, the radiating power of white lead is equal to that of soot. We also found it the same for white and brown skin. The experiment was made as follows: Two entirely uniform tin boxes had their cylindrical surface covered with a double layer of skin in the same manner as the thermometers mentioned a moment ago, while the flat bottom and lid were clothed with a thick heat-insulating felt layer. Both boxes were then filled with water at 45° C., and the cooling of the water was read from the thermometers inserted in the boxes. Care was taken that no cooling was caused by air currents or by evaporation. The result of repeated experiments was that the two boxes—one with the white, the other with the brown skin outside—cooled equally in equal times. Consequently, there is no perceptible difference in radiating power between dead white and dead pigmented skin. There is no valid reason why it should be otherwise with the living skin.

This does not mean that there might not be in any other respect a difference in heat radiation between the two races. In treating of the basal metabolism we came to the conclusion that in the given circumstances the heat production per square metre is the same for the two races. Therefore, this must also be the case with the heat loss. This takes place in the three ways already mentioned, which are interdependent in such a way that the total amount remains the same. To mention an example, abundant perspiration must occasion a diminution of the heat loss by radiation and convection, and vice versa. I have found that in this respect there is really a difference between the two races. In order to make a fair comparison possible, parallel experiments were always made, and with the avoidance of anything that might modify the conditions of heat loss prevailing in ordinary circumstances. The subjects, airily dressed, were in rest during the experiment. We started from the consideration that, if the evaporation of the sweat through the thin, porous clothing of the parts of the skin to be examined could take place in a normal manner, a difference in heat emission by radiation and conduction must betray itself by a difference in the temperature of the air between the skin and its covering. I desist from describing the further arrangements of the experiments, which involved a great many more precautions. A summary of the average results may suffice here.

Temperature of the Air underneath the Clothing.

—	8 A.M.	10½ A.M.	1 P.M.	5 P.M.
	°C.	°C.	°C.	°C.
8 Malayans	32·5	33·4	33·5	33·5
8 Europeans	32·3	33·1	33·2	33·1
Difference	0·2	0·3	0·3	0·4
Room temp.	25·7	27·3	27·8	27·4

The axillary temperature, averaging 36·7° C. in the morning for both groups, rose in the course of the day to 37° C. in the Malayans and nearly 0·1° higher in the whites, a difference which I observed regularly between the two races.

As regards the temperature of the air underneath the clothing just the opposite obtains. The differences are small—they range from 0·2 to 0·4° C.—but they were observed so constantly, also in other experiments than those recorded here, that there is no doubt of their validity. Each time, too, it appeared that the difference became smaller the lower the temperature and the moistness of the air in the room, and would even disappear altogether at 25° and lower. In the experiments recorded, where the room temperature varied from 25·7° to 27·8°, a difference between the two races of 3–7 per cent. in heat emission by radiation and convection may be estimated to answer to the differences of 0·20°–0·4° found in the temperature of the air underneath the clothing. In a higher room temperature they can be much more considerable—e.g., 14 per cent. at 32° C.

As has been observed before, it would follow from the preceding that conversely the heat loss by evaporation of sweat in the Europeans must surpass that in the Malayans. Of course, this could be ascertained by determining the body-weight just before and after the experiment. It is clear that, when under similar conditions in an equal lapse of time a marked difference in loss of weight is found between two subjects, it may for the greater part be put down to an unequal evaporation of sweat.

We found the following average results of 27 parallel experiments lasting 75 minutes each. To make a more reliable comparison possible the subjects had been chosen in such a way that the average body-weight of the two groups was about the same. On an average the European weighing 57·4 kg. lost in moist still air of 32° C., 114 g. per hour; the Malayan, weighing 55·6 kg., 84 g. by perspiration.

Perspiratio Insensibilis.

—	Room temp.	Temp. underneath clothing.	Arm-pit temp.	Body-weight.	Loss of weight.
	°C.	°C.	°C.	kg.	g.
Europeans ..	32	34·6	37·1	57·362	143
Malayans ..	32	35·0	37·0	55·610	105

The difference of 30 g. per hour corresponds to a greater heat loss by evaporation of 16 calories, or just as many per cent. of the total heat loss, if we put this at 100 calories per hour. On the other hand, the Europeans show a smaller loss by radiation and convection, of which there was question just now, and which was estimated at 14 per cent. It goes without saying that this is rather a rough estimation, but our impression remains that the conclusion already arrived at is confirmed, or at least not contravened.

The question now arises whether the white man must evaporate more than the coloured one, because it is more difficult for him to get rid of his body heat by radiation and convection, or is the causal nexus just the other way? I think I can show that the latter is the case. The primary fact is that the heat stimulus incites the sweat secretion in the white more than in the coloured man; hence he perspires more, and consequently gives off less heat by radiation and convection. Yet his sweat secretion far too quickly goes beyond the limits of a rational heat regulation and becomes superfluous. A great part of it does not evaporate, the skin and the clothes become moist. With the Malayan this happens in a far less degree; so long at least as he is at rest he remains pretty dry to the touch, where the white already bathes in sweat. Accordingly, the latter, and especially the newcomer, has much to suffer from lichen tropicus, or so-called prickly heat, a troublesome, itching skin affection, from which the native seems to be exempt.

It is a priori not likely that the sudorific apparatus of the inhabitant of cool countries should be more developed than in the native of the tropics. When we commenced these experiments we were more inclined to suppose the opposite, and made an investigation at the time, which may perhaps be recounted, because of the simple and effective method in which it took place.

After the portion of the skin where the sweat glands are to be counted has been duly shaved, if necessary, and washed with ether and alcohol, it is coloured over a surface of about 20 sq. cm.—e.g., 4 by 5 cm.—with an alcoholic solution of fuchsin. As soon as the skin has become thoroughly dry, which may be accelerated by fanning, a piece of thin note-paper is laid on it without folds, keeping it in position by means of a moderately pressing flannel bandage. After some minutes the paper is taken off, and it will be found to be covered with red spots: the imprints of the sweat orifices. Wherever the paper is dry, indeed, the fuchsin does not come off; but as soon as there appears a drop of sweat from an orifice it dissolves some of the dye and leaves a red spot on the paper. The counting may be facilitated by the use of squared paper, and requires the observation of the same rules as in counting blood corpuscles.

We examined two Malayans and three Europeans. The average values for the various parts of the body are given in the following table:—

Number of Sweat Glands per sq. cm. Skin Surface.

—	Skin on—	Malayans.	Europeans.
1	Palm hand.	299	298
2	Glabella.	171	172
3	Instep foot.	151	175
4	Forearm (extensor side)	160	146
5	Forearm (flexor side)	162	166
6	Upper arm.	161	162

Taking also into account the individual fluctuations among the same race we may conclude that there is no perceptible difference between the two races in the number of sweat glands.

Even taking his smaller body-weight into account, the Malayan as a rule imbibes less water with his food and drink than the white sojourner in the tropics. Now it might be thought that this was essentially the cause of the difference in sweat secretion. This may be true to some extent, but it does not account entirely for it, as is shown by further comparative perspiration experiments. In one of these, lasting three hours, all the subjects were given at the beginning 200 c.cm. water to drink. Then, after emptying the bladder, they were weighed. They now remained at rest in a room temperature of about 30° C., after which they were weighed again and passed the urine formed in the meantime. With about the same average body-weight the white now lost 310 g. by insensible perspiration, the coloured men only 248 g. on an average. Yet the volume of urine at the end of the experiment averaged 130 c.cm. for the former, only 56 c.cm. for the latter.

In the subsequent experiments we gave the Malayans a very plentiful quantity of water to drink, while we kept it entirely from the Europeans, except a few who complained much of thirst, and were then refreshed with a little water. Now, as long as the room temperature was not excessively high, we did not succeed in this way in getting rid of the differences between the two races, much less in reversing them. We found, e.g., insensible perspiration in the white 208 g., against 188 g. in the coloured men; volume of urine 180, against 93 g. Not until the same experiment was repeated—only for a somewhat shorter time, viz., two instead of three hours—in an artificially moistened atmosphere heated to 32·5° C. did the sweating increase so much more in the white that his urine volume was a little below that of the coloured one; insensible perspiration 182, against 158 g., urine 110, against 133 c.cm. To this has to be added the unevaporated sweat, the quantity of which, weighed together with the clothing, amounted to more than three times as much in the thirsting white as in the water-drinking Malayan (average 80, against 25 g.).

That the white sweats more plentifully and produces more urine is not, therefore, merely the consequence of his taking more water; the causal nexus is rather the reverse. As compared with those of the natives, his sweat glands and his kidneys show a greater activity, independent to a great extent of the water intake. He must therefore drink more in order to maintain the water content of his body. No doubt the greater activity of his kidneys is to be accounted for by the fact that he has to excrete nearly twice as much nitrogen as the native.

It is remarkable that notwithstanding this the weight of the Malayan's kidneys in relation to his body-weight is not less than that of the European's. At least, we found as the average of 21 determinations, 260 g. with a body-weight of around 50 kg., while for Europe this figure is stated to be 300 g. with a body-weight of about 70 kg.

Acclimatisation.

We have seen that the old notions formed about the process of acclimatisation have as yet not been confirmed by direct investigation. It has not been possible to prove the existence of what might be called physiological anæmia. In a condition of rest and of moderate labour the metabolism, and consequently the heat production, has been found by us to be on the same level in the two races, and not more considerable in a cool climate than in a hot one. In accordance with the assumption that there is a lack of chemical heat regulation, we see the physical one in the hot environment coming very much in evidence.

The chief objectively perceptible difference between the two races consists in the function of the skin. The coloured man is by his pigmentation better protected against the chemical active rays of the sun, and he is not so subject to excessive sweating. Now, in those two respects there can be, in some degree, a question of acclimatisation for the white, though not to such an extent that he can compare with the coloured man. For the rest it would appear to me that the much-discussed acclimatisation consists rather in an external than an internal process; rather in making, by imitation and custom, a second nature of a manner of living more adapted to the climate than in adequate changes of the bodily organisation as such. Hence, let us have no manner of living, no house arrangements and clothing such as tyrannical fashion prescribes in Europe, and which are but too often slavishly imitated in the tropics. Indeed, the native's frugality both in respect to food and drink, his, as a rule, calm, resigned view of life, his rule of *festina lente*, would deserve, *from a purely sanitary standpoint*, to be set as an example to the white sojourner in the tropics; at the risk, however, of his being after all no more in the full sense the pushing power, so necessary for the development of tropical countries. In the meantime, it would be rash to conclude from the results of comparative race physiology that the former pessimistic views ought to be absolutely relegated to the realm of myths, as some, partly on the strength of my experiments, have already done. The latter are, if I may say so with due modesty, "plus royalistes que le roi." Our investigations in the tropics have been limited to the condition of rest or light labour. What would have been the results could they have been extended to heavy labour, and especially of long duration, which makes higher demands on the bodily functions, and not the least on the compensatory actions? Will not, then, the heat regulation in the white prove to be sooner insufficient, and will not the fatigue, the ultimate exhaustion, set in sooner than in the coloured man? Will habituation, adaptation, training, in short, acclimatisation, appear possible then? These questions cannot be answered, as has been done, by postulating equality, even with regard to the climate, on the strength of anthropological theories. Although we accept the unity of origin of mankind, it will remain, no doubt, true for ever that what ages and climate have separated cannot be brought together again at once by an authoritative pronouncement.

It is true the coloured man, too, does not walk under palm trees with impunity; he, too, suffers from the heat; he, too, is, as a rule, studious of his ease. But still, there is no denying that the atmosphere of the tropics, often so windless, so leaden, oppresses him less than it does the white, to whom continuous mental and physical strain can become quite a torture. There are, indeed, instances of whites in the tropics braving fatigues when out hunting or on military marches, although we must not overlook the fact that not a few have fallen victims to these exertions, or that such strenuous efforts were followed by an ample time of rest. This is not the same as continuous rather heavy labour, even during the hottest part of the day, such as is performed by an agricultural population.

It has been pointed out that on steamers in the torrid zone the European stokers are advantageously replaced by negroes and East Indians. Schmidt, on the contrary, found that with the same amount of labour the negroes were not superior to the whites. He could not discover any difference in the increase of body temperature, the pulse, and the respiratory frequency. Hilger, however, found that after labour in an overheated space the body temperature of a negro returned sooner to the normal than that of a couple of whites. And even Schmidt questions whether, as is the case with the native, the white's working power will in the long run maintain itself in the tropical heat, which is after all the principal thing.

What it really is that makes the heat so exhausting we are far from apprehending. The physiology and pathology of fatigue are still a little explored field. By the adoption of toxins as products of muscle metabolism not all cases are explained, ours among the rest; for fatigue in the heat makes itself felt often immediately after waking in the morning, and is often lessened by slight bodily exercise. The state of weariness and listlessness coupled with psychical irritability, to which the European gradually becomes subject in the tropics, has always reminded me of the syndrome to which has been given the name of neurasthenia or nervous exhaustion. So far it would be better to speak of tropical neurasthenia than of tropical anæmia, only we should then easily form an exaggerated notion of it. If no naturally weak nervous system, no mental or physical overstrain, no illness, no aggravating circumstances of a social or moral nature have contributed their share the phenomena are pretty transient; they disappear as soon as fresher air surrounds us.

Colonisation.

The question whether the colonisation of whites in the tropics is possible in the full sense of the term is not one of a purely hygienic nature. Let us leave alone for a moment the great variety of factors which come into play here, and let us see what mere experience teaches. For more than three centuries there has been a continuous stream of thousands and hundreds of thousands of people going from Europe to oversea lands to which Portuguese and Spaniards have shown the way. And the result? Everywhere outside the torrid zone, and in the countries bordering on it, wherever summer and winter alternate, in North America, South Africa, South Australia, Tasmania, and New Zealand, we see the white race, braving all dangers and difficulties, gain a firm footing, pressing back the native, supplanting him.

How different in the hot regions! The thoroughbred white man attains nowhere any further than to an aristocratic minority. Wherever things seem otherwise, as in the lowlands of Mexico, in some West and East Indian islands, it is not they and their pure descendants who form the real nucleus of the population, but a more or less coloured people, the product of cross-breeding, who here and there, as Réclus has it, by a "complaisance du Fisque" have undergone a "blanchissement officiel." Now I do not wish to argue that the mere fact of unmixed white colonies not thriving anywhere in a tropical climate is a proof that for purely sanitary reasons there is no possibility of their so doing. For, indeed, if the viability of the white race in the tropics remained unimpaired, yet the pure blood propagation in following generations would be no more than an exception, with the manifold opportunities for the mingling of the races. One might, for instance, argue with the same justice that Germans in the long run cannot stand the climate here, because, notwithstanding the many immigrants, nowhere in this country has a German colony come into being. Possibly, too, the special aptitude of Jews for colonisation is not so much due to natural causes as to the traditional custom of keeping their race pure and not allowing it to disappear in the multitude. But it cannot be denied that, whereas the white races dominate nearly everywhere in the temperate zone, in the tropics they get no further than a numerical minority, and this proves at any rate that the native race can engage with much more success in the struggle for life, that, therefore, the superiority of the white race is only a relative one. Indeed, where the native population was thin-sown, it has been necessary to import men from elsewhere, negroes, Indian coolies, proof against hard toil in the hot climate, to supply the urgent need of labour.

Now it will not do to say that it is not so much the climate of the tropics as the diseases prevailing there that handicap the white race in comparison with the native one, for the latter has certainly to suffer no less, nay, often more, from them. The enumeration of the efforts at colonisation of the white race in the tropics is a continuous tale of misery. More than 50 years ago a commission appointed by the Dutch Government, of which the celebrated physiologist Donders was the medical member, gave a sad account of it, and since then experiences have not been more encouraging. Not that a fruitless struggle against the adverse qualities of the climate was the only cause of failure. Complaints of bad preparation, a wrong choice of colonists, inefficient management, want of protection and collaboration, if not opposition, on the part of the authorities were the order of the day. But were conditions better elsewhere outside the tropical regions? Were they all picked people of indestructible health, sobriety, working power, and enthusiasm for work, true pioneers of civilisation, those adventurers who went to populate North America and South Australia? And had in these cases provident authorities taken all the precautions necessary for the success of the colonisation; were political and economical circumstances so much more favourable here? To be sure, no. Nowhere has private initiative in colonisation been supported so much by the authorities as in tropical regions, and if, notwithstanding this, complaints such as have just been mentioned are well founded, it proves all the more how exceedingly difficult it has been to establish such a colonisation, how little in accordance with the natural course of affairs, how much to be considered an artificial culture amidst a freely propagating native population.

Will, in a far-off future, under possibly quite different circumstances, the conditions for colonisation become more favourable? It does not seem at all unlikely to me. Technical skill and industry, backed by science, stick at nothing where there is question of assisting man in the struggle for life. If he cannot be made fit for the climate they make the climate fit for him. I need only remind you of the so-called temperate zone, which has only deserved this name since man has succeeded in making himself to a great extent independent of the inclemencies of the climate, in creating comfortable surroundings by means of adequate clothing, the heating of his house, &c. Why is it not possible that the struggle against the heat should lead to a similar result, though more difficult to attain? Refrigeration in and outdoors, a considerable lightening of the task of the labourers by ever more perfected implements, quicker means of communication which reduce weeks to days, days to hours, and all that at such a moderate cost that it can be generally put into practice—to be sure, it is not indulging in chimæras to believe in this possibility in the future. In this light the question of colonisation is in the first place a technical economical problem, the solution of which may be safely left to time.

Whether this solution is desirable, what consequences it will have for the native, those are questions I do not venture to answer. The spirit of the times is not to be checked in its progress, and hygiene, too, must go with the current, trying by reliable information to contribute its share in leading it in the right direction.

A SERIES OF CASES OF TINNITUS AURIUM ASSOCIATED WITH ABNORMALITIES OF BLOOD PRESSURE.

By H. MORTIMER WHARRY, F.R.C.S. Eng.,
LARYNGOLOGIST TO THE MOUNT VERNON HOSPITAL FOR DISEASES OF THE CHEST; ASSISTANT, THROAT AND EAR DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON.

There are, attending almost every aural clinic, a number of patients who, in spite of having received over a considerable period of time a variety of forms of treatment, nevertheless continue to suffer from severe and intractable tinnitus, which causes them so much distress that their lives are a great burden to them. I have found that the majority of causes of tinnitus are well recognised, and well treated in those cases in which the cause is removable. And in those cases—such as otosclerosis and old head injuries—where the removal of the cause is as yet impracticable, the symptoms are often considerably relieved by bromides in one form or another, or by hydrobromic acid. It cannot, however, be said that bromides are in any sense a curative agent, except in those cases where tinnitus is proved to be due to excessive activity or irritability of the central nervous system as a primary cause. In other cases they merely relieve the symptoms, and in some they do not even do that.

But there is a large group of cases, which, although theoretically recognised by aurists, is not generally treated as an everyday practical problem; and it is this group to which I wish to draw attention, because I have found in it some very severe and distressing types of tinnitus, some of which I have been able to relieve to a considerable extent. I refer to those associated with a blood pressure that is either too high or too low. I believe them to be a great deal more numerous than is usually supposed.

I have dealt with these cases from the point of view of the practical clinician. I have endeavoured to establish a correct diagnosis where other diagnoses had failed, to prove the correctness of the diagnosis, where possible, and to propose a definite line of treatment. I was led to investigate the blood pressure of these patients owing to the fact that they appeared without exception to be of middle age or well beyond. They also appeared to suffer from a degree of tinnitus more severe than is usual in tinnitus from other causes—more severe, in many cases, even than that of otosclerosis. I have divided them into four main groups for purposes of greater lucidity.

Group 1.—*Tinnitus Associated with a Low Blood Pressure.*

Case 1.—Widow, aged 79, complained of very severe tinnitus. Had a considerable degree of deafness—i.e., she could hear the raised voice at three feet. Stated that she could not hear owing to the loudness of the noises, which kept her awake at night. She had had them a long time; and recently they had started to take the form of voices speaking to her. The noise was bilateral. The tympanic membranes were slightly retracted, but repeated Eustachian catheterisation showed clear tubes, and produced no improvement. Months of treatment with bromides had no effect. Tuning-fork tests impossible, the forks being drowned by the subjective noises. Patient conversed in a very loud voice. This case was one of the worst cases I have seen. The tinnitus was gradually producing insanity. Her blood pressure was only 105 mm. of mercury.

Case 2.—Male, aged 54, complained of loud noises in both ears. No deafness, no apparent aural cause; Eustachian tubes clear; patient had no other complaints and was apparently in good health. The teeth were in order. His blood pressure was 115 mm.

Case 3.—Female, aged 41, suffering from severe noises in the left ear which keep her awake at night. They had come on during the last few months. Right ear normal, but in childhood she had a discharge from the left ear. There was now slight deafness in left ear, and an old healed perforation of the membrana tympani with some scarring. Blood pressure 105 mm.

Case 4.—Female, aged 60, deafness and noises, with Eustachian catarrh. Eustachian catheterisation, and treatment of the nose improved both the deafness and the noises, but by no means cured them. Her blood pressure was 115 mm.

It may quite justifiably be objected that because a low blood pressure coexists, with the tinnitus and aural conditions, that it is not necessarily a causative factor. But I regard it as more than a coincidence because of its frequency and because of the following case:—

Case 5.—Female, aged 20, complained of deafness and tinnitus. Paracusis was another symptom. She was suffering from otosclerosis with a marked catarrhal element which disappeared on treatment, leaving a basis of otosclerosis. Her blood pressure was 125 mm. I gave tab. trinitrini 1/100 gr. b.d. for a week purely as an experiment. She returned and said that the noises were infinitely worse, and now kept her awake at night. Her blood pressure had fallen to 105 mm. On leaving off the trinitrin the tinnitus returned to its usual condition, which caused her inconvenience but as yet no serious worry. Her blood pressure returned to normal.

This case shows how the lowering of the blood pressure adds to the severity of the tinnitus in a patient with a normal blood pressure suffering from tinnitus from another cause; and taken with the previous cases proves the causative effect of a low blood pressure.

Group 2.—*Cases Associated with High Blood Pressure Improving on Administration of Trinitrin.*

Case 6.—Female, aged 49, suffering from severe tinnitus and some deafness in the left ear. Left drum definitely retracted, and air entry to Eustachian tube was poor. Tinnitus made worse by exertion, always increased towards end of day, and kept her awake at night. A day of rest always improved the noises. Many months of Eustachian catheterisation, and of bromides, had no effect in improving the noises. Blood pressure 160 mm. She was then given tab. trinitrini 1/100 gr. nocte for one week, and returned to say that the noises had distinctly improved and that she could now sleep well. The trinitrin was then increased to 1/100 gr. t.d.s., and at the end of a month she told me that the noises had practically gone, for which she thanked me profusely. I have not seen her since. Six months later she wrote to say that there was still "some improvement."

Case 7.—Female, aged 62, had no deafness, but had very severe tinnitus causing insomnia. Tympanic membranes only slightly retracted, but some months of bromides and Eustachian catheterisation had no effect. Blood pressure 190 mm. Treated with tab. trinitrini 1/100 gr. nocte, she was able to sleep. After a week of taking it at night she took 1/100 gr. three times a day, until in a month the noises had almost disappeared. She wrote six months later to say that the noises were still "better."

Case 8.—Female, aged 44, complained of slight deafness in right ear, with loud tinnitus which kept her awake at night. Her right ear was disorganised as a result of obsolete suppurative otitis media which had left the tympanic membrane broken and scarred. Administration of bromides had no beneficial effect. Blood pressure was 150 mm. She was given tab. trin. 1/100 gr. b.d., which so much relieved her that she was able to sleep well, and the noises only appeared for one day in every three, and were slight even then. I then did not see her for three months, during which time she took bromides, and the noises reappeared with their old intensity. She was again put on tab. trin. with beneficial results.

Case 9.—Male, aged 68, complained of loud tinnitus in right ear, with occasional giddiness. No deafness. Eustachian catheterisation of right ear produced improvement for two hours only. Air entry quite free. No catarrh. Blood pressure was 190 mm. On taking tab. trin. 1/100 gr. b.d. for one month the noises became very slight, and the giddiness disappeared. Blood pressure was reduced to 175 mm. He returned after seven months because the noises had again become worse. On further administration of trinitrin they again improved. His blood pressure was still 175 mm.

Case 10.—Female, aged 75, deafness and tinnitus in left ear, drum of which was very retracted. She suffered from nasal catarrh. Treatment of nose and Eustachian tubes had no effect, nor was she relieved by bromides. Blood pressure 190 mm. Tab. trinitrini 1/100 gr. t.d. for a fortnight produced no effect. On further administration she did not return, but wrote later to say she was "much better."

Case 11.—Female, aged 61, complained of deafness and tinnitus in right ear, the latter very bad, keeping her awake at night. She was sent by a physician with the statement that her blood pressure was 200 mm., but had been reduced to 166 mm. after treatment with pot. iodide. The drug had not, however, improved the tinnitus or insomnia. The right membrana tympani was scarred from old sepsis, and Eustachian catheterisation showed a free air entry. She was given tab. trinitrini 1/100 gr. b.d., but only took it at night, because in the morning it made her feel giddy. The nightly dose had the effect of enabling her to sleep, and so gave her much relief. It did not, however, improve the noises by day. She wrote three months later to say that the noises had got "very much better," but had again returned with an attack of influenza and bronchitis.

Group 3.—*Cases Associated with High Blood Pressure where Trinitrin had Little or No Effect.*

Case 12.—Female, aged 54, suffering from deafness in the right ear with severe tinnitus and headaches. The drum-head of her right ear was thickened and retracted. Continued Eustachian catheterisation and bromides gave no relief. Blood pressure was 175 mm. On taking tab. trin. b.d. for one week the headaches were relieved, and on continuing for a month the tinnitus was also slightly relieved. On further administration she did not return, and could not be traced later.

Case 13.—Female, aged 59, complained of deafness and severe tinnitus in both ears. Eustachian catheterisation produced only slight temporary improvement, even after treatment of the nose. Bromides had no effect. Blood pressure 190 mm. Tab. trinitrini 1/100 gr. b.d. for two weeks produced no improvement. On further administration she did not return, and could not be traced later.

Case 14.—Male, aged 64, suffered from tinnitus in both ears, with no aural cause. Bromides and iodides had no effect. Blood pressure 180 mm. He was given trinitrin for a fortnight and did not return. He refused further treatment on the grounds that he thought the trinitrin was a purgative.

The cases in this group in which no effect was noticed in a fortnight—i.e., Cases 13 and 14—are unsatisfactory, because on taking trinitrin for another fortnight they did not return. I had noticed in other cases that it was only after a month of treatment that any real progress was produced.

Group 4.—*Cases Associated with High Blood Pressure in which Local Treatment caused Disappearance of the Symptoms.*

Case 15.—Female, aged 63, suffering from deafness in both ears, with retraction of the membranes, and from singing and thumping noises in the head which kept her awake. Her nose was obstructed by polypi. Blood pressure 195 mm. The removal of the polypi and Eustachian catheterisation produced complete relief of the aural symptoms.

I have found two or three other cases in this group whose particulars I did not take, because they seemed to show only that a high blood pressure together with a curable aural lesion does not necessarily cause tinnitus when the aural lesion is cured.

Estimation of the Severity of Tinnitus.

This estimation is difficult, because it is dependent upon information supplied by the patient. It is, however, very important from the point of view of investigation, and a short conversation will usually afford a good idea. I have come to divide them into two groups, the typical "slight" case, and the typical "severe" case. There are, of course, many intermediate cases and an occasional "extreme" case.

Class 1: Slight Cases.—These are divisible into (*a*) those who complain of deafness only, from whom the presence of tinnitus may be elicited by questioning; (*b*) those complaining of slight tinnitus, with or without deafness. Many of these will confess that they believe the tinnitus is always there, but they notice it only when they have nothing to do. They usually forget all about it for most of the 24 hours. It does not prevent them from sleeping. This class forms the majority of all cases of tinnitus.

Class 2: Severe Cases.—The hall-mark of this group is insomnia. It consists of those who, whether deaf or not, say they would not mind anything if only they could get to sleep and forget the terrible noises in the head. They may either volunteer the statement, or disclose it without any too particular questioning, but there is very little doubt of them, as distress and anxiety are plainly written upon them. They are very neurasthenic, but the neurasthenia is the effect rather than the cause of their trouble, and disappears under successful treatment of the condition causing it. There are one or two extreme cases who are eventually driven to suicide or lunatic asylums by the ceaseless horror of noise that will not leave them. Of this type is Case 1.

All cases reported here are either of the "severe" or "intermediate" type, with one "extreme" case. None of them are "slight" cases. I am glad to say that it was some of the "severe" cases who received the greatest benefit.

Treatment.

1. Treatment of the aural disability. I believe this to come first, because in certain cases—i.e., Group 4—the treatment of the local condition may produce a rapid and complete cure.
2. Treatment of cases of low blood pressure. It seems obvious that if the low blood pressure is the cause of the trouble, as I believe it to be, then the correct line of treatment is to hand the patient over to a physician to raise the blood pressure. Bromides may relieve symptoms slightly.
3. Cases of high blood pressure. I think that after the aural disability is treated these also are best controlled by a physician, with occasional reference to the aurist.

Trinitrin.—I used tabellæ trinitrini at first purely for purposes of investigation, but have come to regard it as an essential element in the treatment. My reasons are two:—

1. In Cases 6 to 9 (where trinitrin did most good) the blood pressure was not outrageously high, and the temporary redistribution of the blood to the capillaries by trinitrin had a remarkably beneficial effect, especially at night in enabling the patient to go to sleep.
2. In Case 14 the patient's blood pressure was reduced from 200 mm. to 166 mm. while under the care of a physician, but there was no response on the part of the tinnitus which was as bad as ever. But on taking trinitrin at night she was able to sleep, and her general condition improved.

It is stated in text-books that trinitrin is one of the drugs which produce tinnitus aurium. I have found that it only does so in normal people by reducing their blood pressure below normal; in people with a too high blood pressure the tinnitus is relieved. It is possible that tinnitus in these cases is due to the contraction of the arterioles preventing a full distribution of blood to the labyrinth, and that the relief of this contraction improves the condition. But this is only conjecture. I have used trinitrin because I believe it to be the safest of the drugs producing the same effect in the same way; but I am open to correction on this point.

Conclusions.

1. That cases of severe tinnitus aurium with abnormal blood pressure form a large and important group in which much distress can be relieved. (The number of these cases can be estimated by the fact that I collected some 25 with ease in about three months. Those published, with one exception, represent the first 15 of these. The unpublished ones, of which I have not yet taken full particulars, do not appear to differ materially from the preceding. These 25, however, appear to be largely a residue of undiagnosed, and consequently incorrectly treated cases. Fresh cases only accumulate slowly.)
2. That severe tinnitus aurium may be due to a high blood pressure alone or to a low blood pressure alone, in which case it is usually found to be bilateral.
3. That it may be due to an aural lesion combined with a high blood pressure, or with a low blood pressure, in which case the tinnitus is on the side of the lesion.
4. That in the circumstances just quoted the tinnitus may be cured or improved by removing the aural lesion alone, or by reducing the blood pressure to approximately normal, or by doing both.
5. That trinitrin is of great value as a therapeutic agent in the cases associated with a high blood pressure, as it appears to have a specific effect in relieving the tinnitus.

I hope to make further investigations with regard to tinnitus due to low blood pressure. I have to thank Mr. Harold Barwell for his help and encouragement in undertaking this research; and also Mr. Herbert Tilley and Mr. Lionel Colledge for permission to publish some of the cases.

NOTE ON

THE DIAGNOSTIC VALUE OF X RAY EXAMINATION IN TRAUMATIC INTESTINAL RUPTURE.

BY GRANT MASSIE, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR, GUY'S HOSPITAL.

IN a recent paper on traumatic intestinal rupture[1] attention was drawn to the enormous mortality which attends this accident, and the view was expressed that in at least some cases the detection of a localised pneumo-peritoneum might prove of diagnostic value. The following case, in which the duodeno-jejunal junction was ruptured, is of interest not only because it illustrates the value of this examination, but also on account of the rarity of rupture in this situation.

A Case Described.

Male, aged 52, admitted to hospital on July 2nd, 1923, complaining of severe pain in the abdomen, which followed an injury a few hours previously. While riding his bicycle the patient was struck beneath the left costal margin by the shaft of a milk-cart and thrown into the middle of the road. The pain was so severe that he was unable to get up, and while in the ambulance on the way to the hospital he several times vomited a small quantity of blood.

Condition on Admission.—Patient extremely shocked, rather cyanosed in appearance, complaining of great pain in abdomen and of severe thirst. On palpation, whole of upper abdomen rigid. Liver dullness normal on percussion; no evidence of free fluid in abdomen. Temperature 98° F.; pulse 110 and rather feeble. X ray examination of abdomen showed a moderately large translucent area immediately to left side of second lumbar vertebra (see figure), suggestive of a localised pneumo-peritoneum. No other abnormality was seen.

Diagnosis.—A diagnosis of rupture of the bowel was made, and on account of the situation of the opacity seen in the radiogram it was thought that the rupture had taken place in the highest part of the jejunum.

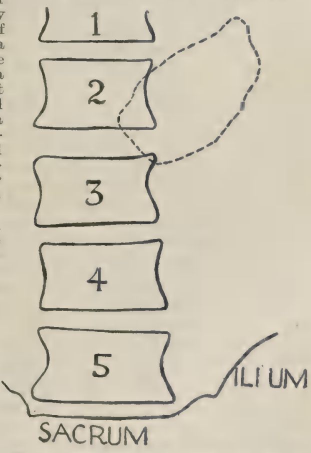

Diagram of X ray plate, showing the relation of the air bubble to the lumbar vertebræ.

Operation.—Operation was undertaken immediately—that is, five hours after the accident. The abdomen was explored through a left paramedian incision, and at first nothing abnormal was noticed. On lifting up the transverse meso-colon, however, a sudden hiss of escaping gas was heard, and on further examination it was seen that the duodeno-jejunal junction was completely divided. A small quantity of blood surrounded the damaged parts, but there had been no escape of intestinal contents and there was no evidence of peritonitis. The third part of the duodenum had retracted behind the peritoneum, which it was found necessary to incise immediately to the left of the superior mesenteric vessels before removing the everted mucosa. In the jejunum, about an inch distal to the injury, a further rupture was found, involving the intestinal wall for about half its diameter. The first two inches of the jejunum were therefore removed and end-to-end anastomosis performed, not without some difficulty owing to the impossibility of bringing the bowel to the surface. The small quantity of blood above mentioned was removed and the abdomen closed in the usual way without drainage. The patient was returned to bed, and in view of his critical condition, which was considered largely due to shock, 10 oz. of citrated blood were given with marked improvement.

The patient made an uninterrupted recovery, and was discharged 16 days later.

Remarks.

The possibility of X ray diagnosis in intestinal injuries was first pointed out in 1916 by Lenk,[2] who, in several cases of gunshot wounds of the abdomen, observed between the liver and the right side of the diaphragm a crescentic air-bubble, which he found to be associated with injury to the stomach or the colon. This author later called attention to a similar condition on the left side, which sometimes obscured the shadow of the spleen and usually was due to injuries in the vicinity of the splenic flexure. Lenk remarks that the suspicion that these appearances were due to injury of the diaphragm and pleura, at operation proved unfounded.

Dandy[3] had recourse to X ray examination of the abdomen in a case in which the diagnosis was obscure, and succeeded in demonstrating a localised pneumoperitoneum, which was later found to be due to the perforation of a typhoid ulcer at the lower end of the ileum. In a further case of the same nature, in which perforation of a gastric ulcer was considered a possibility, Kellogg[4] was able to find an air-bubble above the right side of the liver, similar to that described by Lenk, who had previously suggested that in cases of this nature the examination might prove of some value.

These authorities have all pointed out that free gas within the peritoneal cavity rises within the limits of the cavity to which it is confined, and gas arising from injuries in the upper abdomen finds its way to the diaphragm. In injuries of the lower abdomen this may not be the case and the pneumo-peritoneum remains localised. In the case of the upper part of the jejunum it would appear that the transverse meso-colon and the great omentum form an effective barrier to the upward escape of gas, unless this is of large quantity, which is not usually the case. In these cases the gas tends to pass upwards only as far as the attachment of the transverse meso-colon, appearing, as in the case reported above, near the body of the second lumbar vertebra, whither the attention of the observer should be directed.

The diagnosis of traumatic intestinal rupture is notoriously difficult, the onset of symptoms suggesting peritonitis is usually late, and operative interference is in many cases delayed with disastrous results. It is not contended that the X ray examination should replace the judgment of the clinician, but rather that it should be regarded an an adjunct to the diagnosis of a difficult case.

In many cases naturally the necessary apparatus is not at hand, but at the same time, when it is considered that the mortality of intestinal rupture is about 75 per cent. in hospitals and institutions where every means of complete examination is possible, it is evident that every available piece of information is of importance as a potential factor in the reduction of so high a death-rate.

I am much indebted to Mr. R. P. Rowlands for permission to publish this case.

A CASE OF PROTRACTED DIABETES MELLITUS IN CHILDHOOD ARRESTED BY INSULIN.

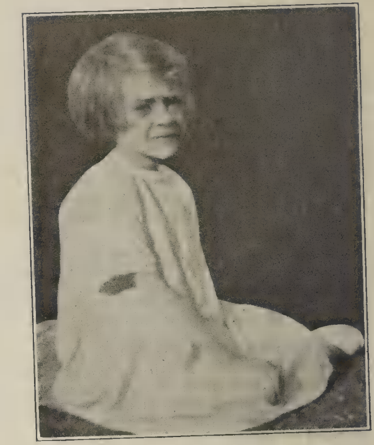
BY W. H. PASSMORE, M.R.C.S. ENG.,

AND

M. O. RAVEN, M.D., B.CH. OXF.

FOLLOWING upon an attack of rubella in March, 1918, this little girl, aged 4 years, developed symptoms of diabetes mellitus—viz., thirst and wasting. In May, 1918, she was examined by Dr. G. F. Still, who found her weight to be 2 st. 3½ lb.; she was thin and pale, and the urine was loaded with sugar. She was put upon a diet, which kept the urine sugar-free, and at the end of four months had put on as much as 7 lb.; her appearance was bright and happy, and a certain quantity of bread and potatoes was able to be included in the diet. During the next 18 months there was little if any deterioration, but the routine of the urine testing carried out at home became less rigid, and she was found to be very poorly in April, 1920, when the urine was full of sugar and contained acetone. The weight was now 2 st. 9 lb. 10 oz., as compared with 2 st. 10 lb. 12 oz. in September, 1918.

FIG. 1.



Appearance of the patient in October, 1923.

Pre-Insulin Treatment.

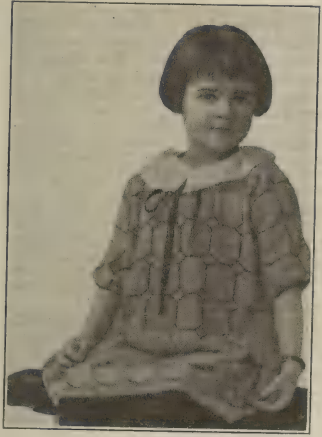
As in 1918, one day's "starvation treatment" rendered the urine sugar- and acetone-free, and by ascending the ladder diet in accordance with Allen's dietary, weight for weight, a diet of nearly 1000 calories was reached without the occurrence of glycosuria. No increase of weight having occurred, the child was rather thin, but was quite active and able to run about and go to school. By October, 1920, 1 lb. had been gained and this weight was maintained in spite of an operation performed by Mr. W. G. Sutcliffe, under open ether anæsthesia, for a suppurating tuberculous gland in the neck; this operation led to no kind of complication and the wound healed well.

During 1921 the weight was maintained, but the food tolerance was steadily diminishing and emaciation was becoming progressive. As much rest as possible was given, but she was still able to run about actively.

In February, 1922, however, within 48 hours of the urine having been sugar-free, a condition of semi-coma developed owing to some dietetic error. The child was very drowsy, intensely thirsty, and had dyspnœa with Cheyne-Stokes variation. Saline given per rectum was not retained, but use was made of the great thirst to give all fluids saturated with bicarbonate of soda, of which a very large quantity was taken. At the end of 12 hours the condition was much improved; brandy was being given, but for a week following the attack no food was given except an occasional egg and raw green vegetables. After a week the urine became alkaline and free from sugar and diacetic acid.

As a result of this illness the condition deteriorated, and by the following April, two months later, the weight had fallen by 3 lb. The condition of the child during the following 12 months became more and more that of an invalid and altogether another 4 lb. were lost. Œdema of the legs and feet came on early in 1922, possibly owing to the intensive treatment with bicarbonate of soda. The face also became slightly œdematous. Emaciation became more and more extreme, and the tendency to bed-sores required constant watching, but fortunately the child was always able to get about gently in the house. Any return of glycosuria as the food tolerance diminished was invariably accompanied by marked acetonuria, so that it was never safe to allow sugar to be passed in the urine for more than a few hours. During this year various forms of pancreatic and hepatic extracts, intestinal antiseptics, raw meat juice, and, externally, olive oil, were used without the slightest effect.

FIG. 2.



Appearance in February, 1924.

In December, 1922, a pancreatic extract prepared by Dr. Mackenzie Wallis was used for two months, and during this time 1¾ lb. were gained; moreover, the constant association between the glycosuria and the acetonuria was changed, so that the margin of safety as regards life was greater. There was, however, no effect upon carbohydrate tolerance. Early in 1923 the worst complication of all occurred in the form of severe neuralgic pain in the head, radiating from the ears, and being fairly continuous by day and night for nearly two months. At this stage the condition was indeed pitiable, and, had it not been for the hope held out by the researches on insulin at Toronto, perseverance in rigid treatment by diet would perhaps hardly have been justified. By the summer, however, the pains gradually left her, and the condition seemed fairly stable again, when Dr. F. J. Poynton saw her with a view to starting insulin treatment. It was then decided that treatment should be started as soon as the likelihood of extreme heat in London should be over.

Insulin Treatment.

Early in October, 1923, accordingly, the child was taken to University College Hospital. Her appearance at this time is shown in Fig. 1.[1] With regard to it, I can only say that the parts covered by clothing gave a considerably more marked appearance of emaciation; the bones of the pelvis were seen beneath the skin in their skeletal outline; the upper arms were almost unbelievably thin. By this time the calorie value of the diet had fallen to 364 and the weight was 2 st.; in five and a half years, therefore, she had lost 3½ lb.

Insulin treatment was successfully initiated and continued by Dr. Poynton and Dr. K. S. Hetzel in October, 1923; except for a fortnight's slight set-back the gain in weight was steady, and in a short time the calorie value was nearly trebled. When the child returned home just before Christmas 9 lb. had been gained; she was no longer an invalid and the deposit of the new subcutaneous fat was a most remarkable thing to see, particularly round the pelvis and the neck. The treatment has been continued since her return home, 16 units of insulin being given before the first and 8 units before the last meals in the day, these two meals containing the bulk of the carbohydrate. Slight insulin reactions have occurred and have been easily checked with a little barley sugar or milk. During an attack of coryza, glycosuria set in suddenly and was dealt with by lowering the diet and raising the insulin dosage. Fig. 2 shows the general appearance in February, 1924; when the patient is stripped the change is much more remarkable.

On April 25th, 1924, the weight has reached 3 st. 9 lb. 12 oz., and the child goes to school every day. The calorie value of the diet is just on 1000 and she is putting on 1 lb. a week still. It does not seem necessary to do many blood-sugar estimations at the present stage; the last one made showed a fasting blood-sugar of 0·16 per cent., as compared with 0·20 per cent. estimated in University College Hospital. The only unusual thing in the child's appearance is the very large size of the abdomen; this may be due to the uneven way in which the new fat is undoubtedly distributed, or possibly to hypertrophy of the intestines following upon the enormous quantity of cellulose ingested during the past six years.

Broadstairs.

SOME OBSERVATIONS ON ENTERIC FEVER IN THE NATIVES OF THE UGANDA PROTECTORATE.

By H. LYNDHURST DUKE, O.B.E., M.D.,
Sc.D. CAMB.,
BACTERIOLOGIST, UGANDA PROTECTORATE.

THE following is an attempt to review the evidence bearing on the origin and nature of enteric fever in tropical Africa, and in Uganda in particular. To the investigator whose work lies in a foreign country and among primitive peoples, the first recognition of one of the diseases of Europe in a native subject possesses a peculiar interest. Questions suggest themselves about the biological relation of micro-parasites to their hosts, and we realise afresh the tremendous efficiency of the "lower organisms" in the struggle for existence.

In the present instance a series of cases of typhoid in natives occurred, within a comparatively short space of time, in and around Kampala, the so-called commercial capital of Uganda. A similar small epidemic occurred in Kampala in 1919, but at that time the material from the cases was sent from Kampala to Entebbe, and not dealt with at the bedside; and although the clinical symptoms and agglutination tests proved the disease to be caused by *B. typhosus*, in only one case was the causative bacillus isolated and that post mortem. The cases described here were more fully investigated. The various medical officers in charge of them kindly afforded me the necessary facilities for making a bacteriological diagnosis, and also supplied the clinical notes reproduced below. I personally visited the majority of cases, and took blood and stool-cultures at the bedside. The absence from the available literature—both text-book and periodical—of any account of enteric fever in African natives has prompted this publication.

---

[1] NOTE.—A member of the Editorial Staff of THE LANCET saw this child in October, 1923, when the condition appeared even worse than that shown in the photograph.

Enteric in the Tropics.

In the interesting historical survey of enteric fever given in Castellani and Chalmers's "Manual of Tropical Medicine," the first description of the symptoms of the disease now known under this name is ascribed to Spigelius, who wrote in 1864. From this date onwards various medical writers described fevers of similar type; but it was not until the early years of the nineteenth century that the clinical conception of the disease, as we now know it, first took form. *B. typhosus* was first recognised by Eberth in 1880. For a time enteric fever was regarded as essentially a disease of temperate climes, but soon after its recognition as a clinical entity in Europe it was reported from various tropical countries—always, however, as a disease of Europeans. Opinions differ as to the origin of enteric in tropical lands—i.e., as to whether it is indigenous or introduced by foreigners. In the case of the older European settlements it is no longer possible to decide upon this point. Some were founded before the nature of the disease was properly appreciated; in others of later foundation the energies of the few available medical men were fully occupied in combating the formidable array of unfamiliar diseases with which they were confronted; so that mild and atypical cases of enteric may well have been overlooked until facilities for accurate diagnosis improved.

The recognition of enteric in the coloured races of the tropics has, it seems, always been preceded by the detection of the disease in the European population of the area concerned. This order of events is easily intelligible. As a general rule, in the early stages of the invasion of their country natives are slow to avail themselves of the help of European practitioners. Time and experience usually overcome their prejudice; but it is the surgeon rather than the physician who first gains their confidence, inasmuch as his successes are the more rapid and arresting. A disease such as enteric, by the very lassitude which it engenders, will probably be allowed to run its course in the seclusion of the patient's own hut. Again, atypical cases of enteric are notoriously difficult to diagnose without assistance from the laboratory; and it is probable that cases of this kind are not uncommon in native communities, where sanitation is non-existent, and where, in consequence, the people are constantly exposed to contact with fæcal organisms. And so it happens that by the time enteric has been recognised in the native population of a tropical country, it is, as a rule, no longer possible to determine whether the disease existed in that country before the advent of foreigners.

Nowadays, cases of enteric in natives have been reported from practically every country in the tropical zone. To all intents and purposes sanitation does not exist among undisturbed native tribes. It is, therefore, difficult to imagine that a disease whose causal organism is eliminated in human excreta, and largely depends on water, flies, and dust for its propagation, can owe its present wide distribution solely to importation from temperate climes. On the contrary, is it not more probable that enteric has always existed in these tropical lands, and that the inhabitants have, in the course of time, acquired a considerable resistance to the disease—at all events, in its indigenous form? Speaking of enteric, Manson-Bahr, in the seventh edition of Manson's "Tropical Medicine," remarks:—

> "It is not unlikely that the relative exemption—if such there be—of the native races is owing to a like immunising effect produced by living in constant contact with typhoid and similar toxic agents, or to an attack in childhood."

Dysentery and diarrhœa are common diseases among the natives of tropical countries. Both the bacillary and the amœbic types have been found, and have a similar geographical distribution. The symptoms of dysentery are sufficiently striking to enable the native easily to recognise this disease, and consequently no doubt the belief exists that dysentery is indigenous to most tropical countries. The symptoms of enteric are less localised, and the disease—especially in its mild or atypical forms—is not likely to hold the attention of the unsophisticated native. It may well be that some of the non-dysenteric diarrhœas so common among native races in the tropics are due to enteric organisms.

Enteric in Natives of Tropical Africa.

We will now proceed to a brief consideration of the distribution of enteric in tropical Africa, concentrating attention finally on the native kingdom of Buganda in the Uganda Protectorate.[1] Standard text-books on tropical medicine afford little or no information on the prevalence and course of the disease in Africans. Cases of enteric in African natives, some of them fatal, have been reported from Zanzibar, Nyasaland, Kenya, Tanganyika Territory, Uganda, Northern and Southern Nigeria, the Gold Coast, and the Sudan in British territory, and also from the French and Belgian possessions. From a perusal of the annual medical reports of these countries the impression is gained that, with better facilities for diagnosing the disease, enteric would be found to be much more prevalent in native populations than is at present acknowledged.

In the annual medical report for Northern Nigeria for 1915 the following passages occur:—

> "It is well-nigh certain that it (enteric) was originally imported by Europeans, and that a number of native carriers have consequently developed since. . . The indigenous native seems to be less susceptible to intestinal disease than is the average European, and this probably explains why native outbreaks have not attended every European case" (of enteric).

In the same series, the report for 1917 contains the following references to enteric:—

> "West African natives constitute a particularly dangerous type of dysenteric and enteric carrier; they are themselves so tolerant of abdominal affections that they not infrequently can carry on easily whilst in a condition which would inevitably prostrate any European."

Dr. C. J. Wilson, acting deputy principal medical officer, Kenya Colony, has kindly supplied me with the figures for enteric for that colony for 1922. The total reported is 38, comprising Europeans 24, and natives 14; native deaths, 2. He remarks:—

> "Of the 14 native cases, 12 were reported from the native hospital, Nairobi. This, to my mind, indicates that enteric may be much more prevalent amongst natives than the figure of 14 for the year would suggest, for accurate diagnosis of a doubtful case is more likely to be made at Nairobi than elsewhere; at other stations cases might easily be overlooked. In my own experience with native carriers during the war, in one month of 1915 I discovered six cases of enteric fever post mortem, not one of which would have been suspected from clinical observation."

From these reports it is evident that enteric occurs in natives in various parts of tropical Africa, and that local medical opinion credits the native with greater powers of resistance than Europeans possess. The mortality of the disease in natives is, however, fairly high—probably owing to the fact that only severe cases are recognised.

Enteric in the Kingdom of Buganda.

Arrival of Foreigners in Buganda.—At the moment of writing the Protectorate of Uganda consists of five provinces, one of which, the Buganda Province, is coterminous with the ancient native kingdom of Buganda. For centuries before the advent of Europeans into the interior of Africa, Buganda was the seat of a civilisation far superior to that of surrounding countries. The social and military organisation of the people was astonishingly complex and efficient, and under a long line of despots the country had for ages dominated its neighbours and maintained complete independence. Hundreds of miles of wild Africa, untraversed by any navigable waterway, lay between Buganda and nearest sea-coast. To the north, across the present Nile route to the sea, lay the hostile kindred race of the Banyoro, whose tribal organisation was almost as powerful as that of the Baganda themselves. To the west lay the Congo with its huge forests and cannibal tribes—an efficient barrier against encroachment from the West Coast. Owing to the geographical isolation and the difficulties of approach, it was not until 1845 that the Arabs, who had been gradually working inland from the East Coast, arrived in Uganda from the south-west. Speke, the first European to reach Buganda, arrived at King Mutesa's court near Kampala in 1862, stayed for six months, and departed home via the Sudan. Baker entered Bunyoro in 1864, and again in 1872; he did not reach Buganda proper. Stanley visited Mutesa in 1875. The first missionaries—three in number—reached the country in 1877, by which date the Arab traders had considerably increased in numbers. The first Indians to reach Buganda arrived in a small detachment during the 1897–98 rebellion, a strong body of Indian troops following later in 1898.

---

[1] Various prefixes to the root "*-ganda*": *Lu-*, *Bu-*, *Mu-*, *Ba-*, &c., denote, respectively, the language, the country, a native and natives of the kingdom of Buganda. *Uganda* is, strictly speaking, the Swahili equivalent of *Buganda*, but has become synonymous with the Protectorate as a whole.

The above is a brief sketch of the invasion of Buganda by Arabs, Europeans, and Asiatics. These newcomers may have introduced diseases foreign to the country, but it must be remembered that none but the strongest could survive the trying ordeal of the long march up from the coast. There is, of course, the possibility that there were "enteric carriers" among these foreigners or their dependents. On this point nothing definite can be said. The only relevant comment that suggests itself is that such a carrier would have constituted a grave menace to his travel-companions during the 700-mile journey from the coast, and under the necessarily primitive living conditions imposed on the newly-arrived missionaries at the Buganda capital. Under such circumstances the absence of evidence that the pioneers suffered from any epidemic disease suggestive of typhoid has, perhaps, some slight bearing on the issue before us. All this is, of course, pure speculation, but so also is the introduction theory.

Recognition of the Disease in Buganda.—From these early days up till the arrival of Dr. A. R. Cook in 1897 no great expansion occurred in the foreign occupation of Buganda. Hardly any information is recorded about the diseases of the country during this period. Dr. Cook started work immediately on arrival, and very soon the nucleus of the now famous C.M.S. hospital system was established at the capital. From the outset careful records have been kept. Dr. Cook, with unfailing readiness and kindness, has sent a brief note on the earliest recognition of enteric in Buganda. He writes as follows:—

> "The existence of enteric fever was long denied in Uganda by some of the very few medical writers practising there in the late 'nineties and the early years of this century. Careful in-patient records have been kept at the C.M.S. Hospital, Kampala, since June, 1897, but in those pioneer days, when the railway had only advanced a few miles from the coast and it meant a three months *safari* to reach Uganda equipment had to be cut down to the utmost limits. Obstacles were constantly thrown in our way over the conduct of post-mortem examinations. Though begged for almost on bended knees from the relatives, and the advantages to the living constantly pointed out, they could but rarely be done, and then, as it were by stealth, some five post-mortems only were performed in the first three years. Enteric fever was again and again suspected in natives—.g., one man died from a perforating ulcer of the intestine, nother from hæmorrhage from the bowels; many showed linical signs of the disease, but it was not till 1901 that fortunately-obtained post-mortem in a native showed erfectly typical typhoid ulcers in the small bowel. The pecimen was kept in spirit and shown to unbelievers for ome years. When Colonel (now Sir) David Bruce came to he country in 1903 on the Sleeping Sickness Commission e confirmed the opinion that the ulcers were genuine yphoid ulcers.
>
> In the practice of this hospital cases have always been are; there has never been a general epidemic. As examples f clinical typhoid the following may be cited. I attended Irs. L (European) in March, 1900, while on *safari* to Toro, journey which then took a fortnight. She was attacked y a continued fever, lasting rather over three weeks. She owed rose spots, and miscarried after a fortnight. She had a relapse accompanied by pneumonia, and all but died—her husband starting in to make her coffin. She is still alive and well. . . . I was in close attendance on this unfortunate lady, and, a fortnight after leaving her, started a severe attack of what I took to be enteric. I had continued fever for six weeks with 'tender toes,' quite uninfluenced by quinine up to 55 gr. per diem, and complicated by phlebitis."

From the above it is plain that the disease was sufficiently prevalent in Buganda in 1897 to attract the notice of the first expert who came into close professional contact with the natives.

At the present day the Baganda have no special name for enteric fever in its typical form. The enteric syndrome is covered by the term "omusuja" (fever), the local equivalent of "P.U.O." In the list of diseases that are recognised by the Baganda themselves, though not specifically named by them, there are certain more or less prolonged fevers, accompanied by headache, lip sordes, and dirty tongue, that are usually followed by recovery. Probably some, at any rate, of these fevers are due to enteric organisms. As already mentioned, the conditions in native villages appear at first glance to be most favourable to the spread of this disease. Although the Baganda are relatively clean in their habits, washing their hands before and after eating, and taking care about the cooking of their food, yet they are ignorant of the very rudiments of modern sanitation and hygiene. The water they drink is usually opaque, and is never boiled. The vast majority of the village sources of supply are unprotected surface springs, or holes dug indiscriminately in swamps. The sun is, no doubt, a valuable ally. Springs which even a layman would condemn after the most casual inspection of the vicinity yield water the bacteriological content of which is considerably lower than would be expected from a similar source in temperate climes. There are, however, limits even to the sun's powers; and, on general grounds, one would expect that a race living under such conditions would possess a high degree of resistance to fæcal organisms of all kinds, whether introduced through the skin as in wounds or by the mouth.

In one respect the Baganda have benefited by the geographical isolation of their country. The advance of the foreigner has been slow and on a relatively small scale. There has been no great upheaval in the mode of life of the native, and the changes that have occurred are limited to the vicinity of one or two of the larger settlements. The European community is still small, and the tenor of native life continues in the main on the old-fashioned lines. Carbohydrates bulk largely in the national dietary of the Baganda, and this may to some extent check the dissemination of *B. typhosus* by the fæcal route (Torrey). The so-called towns in Uganda have not developed true "native quarters." There is still plenty of room to move in the Protectorate, and the native keeps, to a great extent, to his villages and retains his old habits.

In this connexion it is significant that where natives are taken from their normal surroundings and crowded together, even though under strict supervision, typical enteric is liable to appear.

Observations.

Of 11 cases of enteric in natives of the Uganda Protectorate occurring at Kampala between June and November, 1923, 2 died (a mortality of 18 per cent.). Their case-histories show that the natives of the Protectorate are liable to attacks of a typical enteric fever. Both deaths were of prisoners in gaol; both men had malaria. Dr. Wilson's experience, quoted above, of fatal cases in British East Africa, related to native porters during the war. In each instance the individuals affected were leading an abnormal existence, under conditions inevitably more or less unfavourable. In the Kampala epidemic of 1919 most, if not all, the cases originated in the gaol.

No doubt a variety of factors combine in determining these outbreaks. The gaol population comprises natives of different races, habits, and constitutions, and weak and strong are in close daily contact; the gaol is dependent on roof or spring water, and it is exceedingly difficult to guard against dust contamination. However well organised and supervised, prison life is prone to exert a depressing effect on the general vitality, and natives are very susceptible to psychical influences and changes in environment. The presence of "carriers" is difficult to detect, and the power for evil of a "carrier" under such conditions is very great. On the first recognition of enteric in the gaol this year the sera and stools of the seven native cooks were examined for evidence of typhoid infection. Two gave complete agglutination in 1/50, and one of these + + in 1/100 with *B. typhosus;* none of the stools yielded the bacillus. Under the circumstances the wonder is not that occasional cases of enteric occur, but that the disease and its congeners are so rare.

No cases of enteric in Europeans have been reported from Kampala during the last few years. Cases occur at rare intervals in up-country stations, indicating a wide distribution of the disease within the Protectorate. The rarity in Europeans is to be explained by the fact that the community is small, that there is still plenty of space, and that the sanitary organisation, though simple, is efficient.

It is at present impossible to pronounce on the prevalence of the disease in natives of the Protectorate. Much investigation is needed, and time and staff are limited. Up to the time of writing, sera from 246 natives attending Mulago Hospital for venereal disease have been tested by the macroscopic method for agglutination against *B. typhosus* and the paratyphoids A and B, the dilutions used being 1/50 and 1/100. Agglutination occurred in three instances, in each case complete in 1/50 and + 1/100, with *B. typhosus.* Sera from 26 other natives, patients in the Kampala hospitals suffering from undiagnosed fevers, gave no agglutination with the enteric organisms. The great majority of these sera came from adult persons of both sexes. According to the views put forward above, in an investigation of this kind special attention should be paid to children and young people, and these are particularly inaccessible. We may conclude from the evidence before us that enteric fever in its typical form is uncommon in Uganda. This is, also, the considered opinion of Dr. Cook, and his opinion carries the weight of 26 years' experience of the ailments of all classes in the Protectorate.

The evidence suggests that enteric organisms exist in the native population of the country, but that, under normal conditions of life, the balance between the organisms and their native hosts is well adjusted. Alterations in environment—particularly changes in diet, crowding, and close contact with strangers (white or coloured)—may disturb this equilibrium, and the organism may then assert itself in its classical European form.

Unfortunately the evidence bearing on the origin of enteric fever in Buganda is inconclusive. Dr. Cook recognised the disease before it was suspected by his colleagues of those early days of medical-missionary enterprise; and it is interesting that his diagnosis was based on symptoms observed in native Africans, and not in European patients. The usual order of discovery is thus reversed.

But we are not much nearer the solution of either the general or the local problem. The balance of probability seems to be in favour of certain assumptions—namely, that enteric is a disease indigenous to tropical countries; that the newly arrived European, being racially less inured to dirt (in the broadest sense of the word) than are his less squeamish coloured brethren, and handicapped also by an unfavourable environment, is particularly susceptible; and that the natives of a tropical country possess a relatively considerable resistance, under the conditions of life normal to that country.

My thanks are due to Dr. J. H. Reford, Principal Medical Officer, Uganda Protectorate, for permission to publish these notes; also to Dr. W. L. Webb, Superintendent of Mulago Native Hospital, for his kindness in allowing me access to the material in that establishment.

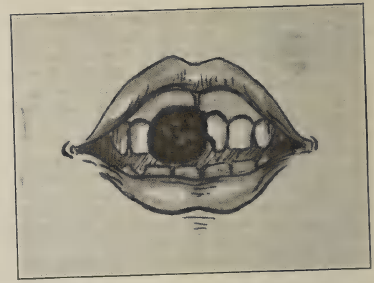
Clinical and Laboratory Notes.

MYELOMA OF THE UPPER ALVEOLUS IN A CHILD.

BY P. B. KITTEL, B.CH. CAMB., M.R.C.S. ENG.,
LATE SENIOR HOUSE SURGEON, METROPOLITAN HOSPITAL, LONDON, E.

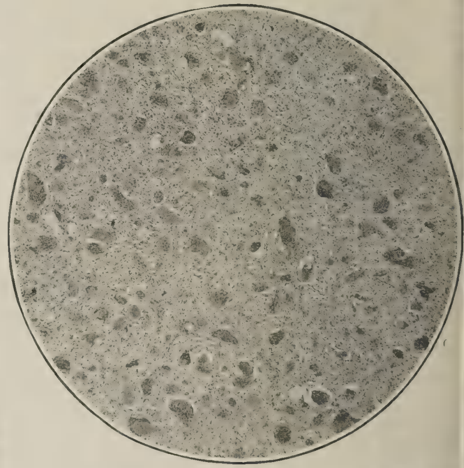
THE following case is recorded as the condition seldom occurs at an early age.

Early in July, 1922, a boy, aged 5½, was brought to hospital complaining of a sore place on his upper jaw under the lip.



Appearance of myeloma.

His mother gave the following history: On May 24tb, 1922, he fell against a wall, knocked out the middle right incisor tooth of the upper jaw, and chipped his left middle incisor. The injured gum gave no trouble and was believed to have healed. But it was noticed later that the site of the lost tooth was becoming filled with a dark red substance. This grew until it became uncomfortable from its size. It was painless and did not bleed. In place of the right middle incisor a flat circular plum-coloured growth was to be seen extending by its edge on the left to cover half the remaining middle incisor on the right, overlapping the lateral incisor and above, one-eighth of an inch higher than the edge of the gum. It has a circular base, limited by the gap between the teeth. The edge overlapped the base all round, and was



Section of myeloma showing giant cells and fusiform cells.

smooth, regular, and firm. It was covered with a film of tenacious slime. The centre was probed, but no portion of dead tooth was felt. An X ray showed healthy bone and unerupted permanent teeth. The appearance is shown in Fig. 1.

Operation.—The growth was excised under general anæsthesia. The mucous membrane was incised close to the base of the growth and the base divided. There was some free arterial bleeding, which was stopped with a suture. The wound healed rapidly and left a firm gum, without scar or irregularity.

The section (Fig. 2) shows giant cells and fusiform cells seen in myeloma. It is interesting to notice here that a cure was produced without interference with the bone; a scalpel only was used to remove the growth.

This type of tumour is well known to occur in the jaws, both within the bone and outside it, but at this age it is uncommon. This one doubtless arose from the soft tissue covering the bone or dental membrane. The boy had no congenital deformity of the face or irregularity of the milk teeth. The growth contained no other type of tissue, save that shown in the section. The tumour reached the size which Fig. 1 indicates, as far as can be known, between May 24th and July 21st, 1922. It had no capsular covering on the surface, yet preserved a button-like shape with a smooth edge. An infected wound seems in this case to be connected with the origin of the disease.

FOUR CASES OF HERPES ZOSTER.

BY H. A. COOKSON, M.B., F.R.C.S. EDIN., D.P.H.

(From the Pathological and Bacteriological Departments, Royal Infirmary, Sunderland.)

THE following cases of herpes zoster are of interest in relation to their occurrence, and tend to support the theory that this disease is really an infective poliomyelitis posterior acuta.

In group A there were three cases, brief notes of which are below.

CASE 1.—Dr. X., aged 34½ years, had a typical attack of intercostal herpes zoster, with neuralgic pains. He had had chicken-pox.

CASE 2.—Mr. Z., aged 30 years, had severe intercostal neuralgic pains (13 days after Dr. X.), with a scanty eruption, not so closely limited to the intercostal nerve involved as in Dr. X.'s case. Mr. Z. had had chicken-pox in childhood.

CASE 3.—Dr. Y., aged 38 years, developed herpes zoster 14 days after Mr. Z. The intercostal neuralgia was fairly severe, and the eruption, although less marked than in the case of Dr. X., was more marked than in that of Mr. Z. There were also one or two vesicles in other parts of the body and the neuralgic pains continued a considerable time afterwards. Dr. Y. had had chicken-pox as a boy. He also had a leucocytosis of lymphocytic type.

The persons concerned in this small outbreak were all in fairly close contact at their work daily, and it appears that they infected each other. At the same time there was a fair amount of chicken-pox in the district in which they lived, the outbreak of chicken-pox being at its height when these herpes cases occurred. It will be noted that all the persons in Group A had had chicken-pox previously.

In Group B there was one case.

CASE 4.—Dr. L., aged 58, 14 days after seeing a patient with herpes zoster, contracted the disease in the supra-orbital region. He was severely attacked with great pain and a considerable eruption, the neuralgic pains persisting. He had had a previous attack of herpes zoster 20 years before.

These cases, unfortunately rather scantily observed, are very suggestive of herpes zoster being an infective disease, on the lines of poliomyelitis anterior acuta—the incubation period being possibly 14 days. Apparently the chances are that chicken-pox had no relation to the attacks; and it is noteworthy that in the case in Group B immunity from the disease did not remain permanent.

Medical Societies.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society was held in the rooms of the Medical Society of London on April 25th, the chair being taken by Mr. DENNIS VINRACE.

Neuro-recurrence after Arsenobenzol.

Mr. E. R. T. CLARKSON, the hon. secretary, said that out of 34 replies to the questionnaire addressed to medical officers of military hospitals concerning cases of neuro-recurrence following the administration of arsenobenzol only one such case was reported, and that was in a private patient. One well-known syphilologist, however, had written in a general way, without giving any cases, contending that there had been an increase in nerve syphilis following the newer methods.

Bismuth Therapy in the Treatment of Syphilis.

Major A. T. FROST, R.A.M.C., opened a discussion on this subject. He said that in 1921 Sazerac and Levaditi reported the result of treating five cases of syphilis by means of tartaro-bismuthate of potassium and sodium, and since then much work had been done on the subject. In this country, so far, little desire had been shown to desert the arsenical compounds for the newer preparations, and rightly so. Among the preparations on the market it was difficult to choose the one which combined an efficient dose in reasonable bulk which was painless, did not encyst in the tissues, and was absorbed into the general circulation at the right pace. The tartaro-bismuthate of sodium and potassium was too painful for general use, and the substance which became popular owing to absence of pain and induration, the iodo-bismuthate of quinine, had too small a bismuth content, varying from 24 to 50 per cent. of metal. The simple salts of bismuth, such as the hydrate and the chloride, contained 80 to 90 per cent. of the metal. The oxychloride could be given without causing pain when properly made, and 2 c.cm. of it bore a sufficient dose. Major Frost thought it would be better if the dosage could be got into 1 c.cm. Its absorption was even and not too quick or too slow. There were many trade preparations of the metal in a finely-divided state, and the highest percentage of bismuth in them was 97. Some said these were painless, others that they had had to stop the injections because of pain and indurations. He had himself received complaints of pain five or six days after the injection, and of a painful node at the injection site. If, however, the injection passed directly into the muscle sheath, and the skin was pinched as the needle was withdrawn and held for a short time, no complaint was made. He did not think the healing activity of the best bismuth preparation was likely to be greater than that of the arsenobenzol group. He urged that there should be an abandonment of the present haphazard methods of preparation, and the adoption of a standard based on definite physiological and chemical laws. With bismuth in liquid suspension it was too dangerous, in clinics, to take a dose from a bottle when accuracy depended on the vigour of agitation of the bulk while the dose was being withdrawn. With a semi-solid suspension this difficulty was not so pronounced as with mercurial cream, as the bismuth was unaffected by overheating, and most of the salts were sterilised at 120° C.

Bismuth was slow in healing up the active signs of disease in comparison with arsenic, and that fact militated against its use in venereal clinics except as an adjuvant. The most which could be claimed for the drug in the early stage of primary syphilis was that an originally negative Wassermann reaction did not become positive during the course. It was of great use in relieving painful symptoms in the late nervous stages. In one of his own cases which had shown no improvement under arsenic the man began to lose his pains after four injections of bismuth, and in a fortnight resumed his ordinary work. After one or two doses bismuth could be recovered from the cerebro-spinal fluid, hence it was reasonable to regard it, when combined with arsenic, as an important protector of the central nervous system against attack by the *Spironema pallidum*. He had not yet seen a case which could not take bismuth. Some patients developed albuminuria early in the treatment, but it cleared up after 14 days' cessation and did not return on resuming the treatment. He had seen only one case with definite inflammation of the gums, though most of the cases showed a black line on the dental edge of the gums all through the course of combined arsenical and bismuth treatment. Cases intolerant to arsenic he had continued to treat with bismuth, and without untoward effect, but without a positive blood test becoming negative, and he asked whether, in such cases, a more intensive bismuth course should be given. So far he had not exceeded 9·2 g. of the metal weekly. His method during the past year had been to give a first series of seven injections of stabilarsan and seven injections of bismuth in 57 days, repeated after an interval of a month, and 14 days of potassium iodide just before the second series. At present he did not think one could go further than to state that bismuth therapy was superior to mercury therapy for primary, secondary, and tertiary lesions of syphilis when either was combined with arsenobenzol. He did not think "bismuth-fastness" was likely to occur. The fact that bismuth was ten times more toxic by the veins than when given by the intramuscular or the subcutaneous route was a drawback. As a safety test he first plunged the needle into the injection site, then if no blood came from the needle butt he attached the syringe and applied negative pressure by pulling on the piston while the hand holding the syringe was fixed against the buttocks. Colloidal bismuth was probably highly active for a short time in the blood-stream, but it soon became inert as a colloid and then merely acted as a minute amount of metallic bismuth in the body. There were, the speaker concluded, three metals in the lists in the fight against syphilis, of which the latest had made a bid for second place. It had been suggested to him that cadmium might be useful in the same connexion. The more drugs of high curative and high sterilising power there were available the better, for then the clinician had more scope in cases in which individuals showed intolerance to any one drug.

Discussion.

Colonel E. T. **Burke** said that the preparations he preferred were neuthanol, iodo-bismuthate of quinine, biquinil, and luatol. No stomatitis, nephritis, nor any injection lesion occurred after them, in his experience. He agreed that bismuth displaced mercury as an antisyphilitic. His present practice was to alternate bismuth with stabilarsan, discarding mercury. He did not think arsenic should yet be discarded in favour of bismuth. Arsenic and bismuth should not be given concurrently, but in alternative courses. During the last 18 months he had treated 23 cases which were apparently drug-fast to arsenic and mercury, for the Wassermann remained positive. He treated them with iodo-bismuthate of quinine, and 12 of them now gave a negative Wassermann, though in two the cerebro-spinal fluid remained positive to that test. The great value of bismuth lay in its efficacy for cases which proved to be absolutely intolerant of arsenic.

Captain C. **Doble** expressed his agreement with Major Frost concerning cases which had persistently given a positive Wassermann under ordinary treatment becoming negative under bismuth. He related some cases in which under treatment with arsenic compounds the Wassermann remained positive many months, but quickly changed to a negative response under bismuth. There was an objection among makers to putting up the bismuth preparations in greater quantities than 1 oz. ampoules because of the results of the entry of air each time the vessel was opened and the danger of the metal sinking to the bottom. He thought this objection was fully justified.

Dr. **Herschell** said he began to use bismuth 18 months ago, the neotrepol preparation, which contained 96 per cent. of the metal. He had, however, abandoned it for mercury because it caused so much stomatitis, probably largely because most of the mouths of his patients, mostly Hindoos and Chinese, were very dirty. He agreed, however, that bismuth had a quicker and more certain effect in rendering a positive Wassermann negative. He asked how bismuth could be used for a case of tabes without causing stomatitis.

Mr. **Wansey Bayly** said his use of bismuth had been limited to neotrepol. In a year he had experienced no difficulty in regard to stomatitis. At present he was treating a case of tabes with it, and was pleased with the result, for the plantar reflex had returned, and the patient no longer had the feeling of walking on a soft carpet; in addition, the areas of anæsthesia and hyperæsthesia in the legs had vanished. He had not tried bismuth alone for early cases of primary or secondary syphilis. Bismuth was well worth trying.

Dr. A. M. H. **Gray** said his experience with bismuth preparations was somewhat limited. He found that the ordinary out-patient would not stand the large doses which some people recommended. Most mouths would not tolerate more than 2 c.cm. of neotrepol in ten injections. In one or two cases severe stomatitis compelled a cessation of the treatment. Cases in which N.A.B. or stabilarsan was interspersed with salvarsan showed improved results in comparison with those in which mercurial treatment was used in alternation. He quoted a case which was very intolerant to both arsenic and bismuth but who had no toxic symptoms and was greatly improved on luatol.

Dr. **Margaret Rorke** said patients complained definitely of pain after neotrepol. During the last six months she had used quinine iodo-bismuthate, and it gave very good results. In conceptional syphilis of old standing in women she found alternations of bismuth with arsenic very useful in lessening the danger of arsenical poisoning at those times.

Major **de M. Peyton** said naval medical authorities found that in a number of cases of active primary and secondary syphilis treated by bismuth preparations alone not only did not the positive Wassermann become negative, but secondary signs of the diseas supervened in spite of intensive bismuth treatment But in some cases treated with arsenical preparation in which arsenical complications occurred, the resor to bismuth was extraordinarily successful. At St Thomas's clinic much disappointment was felt at th lack of destruction of the spirochætes in active syphili by bismuth; but they had formed a high opinion o luatol, which he regarded as an excellent antisyphiliti remedy. But the pain it caused had forced its abandonment. Entry of air into the bottle containing th preparations could be prevented by using rubbe capped bottles. Bottles of 25 c.cm. capacity wer used. The bottle was inverted and the contents kep in a state of agitation while the syringe was receivin its supply, and the rubber cap immediately seale the neck when the supply had been withdrawn.

Major **Frost**, in reply, said some organic salts seeme to be more effective than others. Perhaps he did no meet with much stomatitis because soldiers were s carefully nursed and looked after in regard to their teet and mouths. The presence of the black line along th teeth margins was not an indication for stopping th treatment. He felt that bismuth, arsenic, an mercury were three drugs which depended for the action on their conjunction with some substance in th body, and the complemental substance to one of the might be missing in some patients, for whom, therefor one of the other three metals would be efficacious.

An Interesting Case.

Major **Peyton** showed a case of Chronic No progressive Anterior Poliomyelitis of Specific Origi The patient, a man aged 57, contracted syphil

35 years ago, and his treatment consisted of a 90 days' course of mercury pills. Eleven years ago there was a decrease of muscular power, with some wasting in the arms and legs. In 1916 he had three injections of "606," after which his walking improved. Three years later he again had three injections of "606," but no subsequent treatment of any kind. The condition was apparently stationary until a year ago, when he had occipital headaches and experienced a warm patch between the scapulæ, and he has now lost all power in both thumbs. Deep reflexes are exaggerated, the plantar response is flexor, but sensation is normal and there is no sphincter disturbance.

DERBY MEDICAL SOCIETY.

A MEETING of this Society was held on April 10th, Mr. J. E. KILVERT, the President, in the chair, when a paper was read by Dr. JOHN A. WATT on

Intrathoracic Tuberculosis in Children.

Dr. Watt said it was now generally accepted that tuberculosis in adults developed from an infection in childhood, and that all efforts at prevention should begin in early years. Investigations by the Royal Commission and others showed that human tubercle bacilli were almost constantly present in pulmonary and bronchial gland tuberculosis, indicating that infection occurred from human sources. The clinical features of intrathoracic tuberculosis were dealt with in three main forms—viz., (1) general or infantile, (2) hilum or juvenile, (3) adult types. Tuberculosis in infancy showed a strong tendency to generalisation and was most fatal at this age. The bronchial glands were invariably involved and were usually the chief entres of the disease. Progressive caseation occurred, hen dissemination, and miliary tuberculosis or neningitis was the termination. The typical form in nfants was acute miliary tuberculosis; other varieties vere tuberculous bronchitis and caseous pneumonia. When school age began the disease passed into more atent and chronic forms with a low death-rate. The ommon form was a benign and latent glandular nfection contracted in infancy. The primary lung ocus gave rise to secondary infection of the thoracic lands, but the disease might spread out into the arenchyma of the lungs. This condition was known s hilus tuberculosis, and by the French as "glandulo-ulmonaire." The physical signs of hilus disease ere discussed and most importance was attached to ara-vertebral dullness, altered breath sounds, and 'Espine's whisper sign. Radiography was invaluable, nd the presence of tubercle bacilli clinched the iagnosis. A case of open tuberculosis in a household ad a sinister influence on young life. Investigations owed that in such nearly all infants were infected the first four years of life. Hilus tuberculosis was sually a mild disease and nearly all cases recovered. might smoulder on for years often unrecognised, d there was weighty evidence accumulating that lus tuberculosis in children might develop at olescence into the adult type as we knew it. Adult pes, apical, basal, or lobar, were not common before e age of 12 but increasingly frequent afterwards. ey were easily diagnosed, tubercle bacilli were ually present, and a radiograph showed the extent the disease.

Dr. Watt tabulated 165 cases of intrathoracic berculosis admitted to the County Sanatorium ring the last four years. There were 117 cases of us tuberculosis with one death, and 48 cases of ult forms with 18 deaths after an average period of ee years. Fifty per cent. of the hilus cases had ercle bacilli present and nearly 80 per cent. of the lt cases, examination being made by the Ellerman-andsen method. Lantern slides were shown of iographs illustrating the main types.

A discussion followed, in which there took part S. BARWISE, NIVEN ROBERTSON, H. BARBER, PARRY-JONES, F. G. LESCHER, and P. HEFFERNAN.

Reviews and Notices of Books.

MEDICINE, MAGIC, AND RELIGION.

By W. H. R. RIVERS, M.D., D.Sc., F.R.S. Preface by G. ELLIOT SMITH, F.R.S. London: Kegan Paul, Trench, Trübner and Co., Ltd.; New York: Harcourt Brace and Co., Inc. 1924. Pp. 147. 10*s.* 6*d.*

How great was the loss sustained by psychological medicine through the untimely death of Prof. Rivers is proved by the publication in book form of his FitzPatrick Lectures by the International Library of Psychology, Philosophy, and Scientific Method. The lectures were delivered before the Royal College of Physicians of London in 1915–16, and were reported in full in THE LANCET, where they were seen to display in a simple manner the intimate relations between primitive medicine and magic and religion. The author takes the widest possible survey of the ways and thoughts of primitive medicine-men, and while in many places the deductions are distinctly original, the copious references to other authorities show how well Prof. Rivers was documented. Nowhere is the volume padded out by quotations; for example, he does not consider the kind of magic usually known as sympathetic magic in any detail at all, but refers the reader to the magic art of Sir James Fraser and his own great monograph on the history of Melanesian Society. The work of A. B. Ellis, E. im Thurn, C. G. Seligman, and J. Roscoe comes in for similar allusive treatment.

Prof. Elliot Smith points out that in the last years of Rivers's life his views were undergoing a change in the direction of a fuller recognition of the part played by the diffusion of culture in the development of custom and belief. The first two chapters of the book, which represent the first two lectures, were written after Rivers's valuable work at the Maghull Military Hospital, where for a considerable period he investigated the mental effects on soldiers of trench warfare. He then found a remarkable analogy between the methods employed in the hospital for the diagnosis of psychical disabilities and those which he had used himself in Melanesia when investigating the social and religious practices of primitive peoples; and in the second chapter the section treating of the attribution of disease to infraction of taboo, quoted from a book by Mr. A. M. Hocart and himself recording their studies in Mandegusu, indicate how keenly Rivers was interested in the effects of cultural diffusion upon the psychology of races. The last chapter of the book, entitled "Mind and Medicine," considers at length an important principle of psychological medicine—namely, psychical determinism—and contains the author's views of the work of Freud, of whom he says that more than any other investigator he has emphasised the mental factor in disease. The early relationships between man and medicine are shown in this chapter to be bound up with the process by which medicine grew out of magic and religion. This closing essay formed the subject of an address delivered in 1919 at the John Rylands Library in Manchester, and makes a valuable round-off of the whole subject, indicating well Rivers's own development of outlook.

SURGICAL EMERGENCIES.

By RUSSELL HOWARD, C.B.E., M.S., F.R.C.S. Eng., Surgeon, London Hospital; Senior Surgeon, Poplar Hospital. London: Edward Arnold and Co. 1924. Pp. 216. 7*s.* 6*d.*

"Emergency surgery has therefore become decentralised and the general practitioner . . . is now called upon to perform operations which a short time ago were in the hands of the surgeons of the great hospitals." The truth of this statement in the author's preface cannot be denied, though we may disagree with the reasons he assigns therefor. If operative treatment at local small hospitals is to be of a high standard, then the presentation in concise form of usually accepted methods of diagnosis and treatment is urgently needed. Since such a handbook as this is designed to reach men in country practice who have little if any time to check the truth or soundness of what they read by wide visual experience of other methods, it is more than ever essential that the methods of diagnosis and the choice of operative procedures should be above reproach.

We sympathise with the motives which prompted Mr. Howard to write this book, but confess to disappointment with some of its contents. The book contains a very great deal that is admirable in every way—e.g., the chapters on abdominal injuries, head injuries, and the urethra are full of sound advice. But other sections are less satisfactory. In dealing with blood transfusion, there occurs the sentence: "In cases of emergency, however, the risk of producing intravenous clotting may be taken" (p. 13). When the testing of blood groups (not explained in the text) is so simple a matter, it must border on culpable negligence to give a blood transfusion if the groups of donor and recipient are not known. Again, in discussing acute osteomyelitis, Mr. Howard says: "The physical signs are a deep-seated brawny swelling near a joint." He does go on to say that the diagnosis may be made by a point of exquisite tenderness; but the whole aim and object of the surgeon should be to diagnose the case long before swelling occurs, for the prognosis in such neglected cases is appalling. In the treatment of this condition the author still scrapes out the marrow and with it the endosteum with a sharp spoon, and to complete matters swabs the cavity with pure carbolic. The lesson taught by Nichols in Vol. II. of Keen's Surgery has evidently not yet been accepted by him. On p. 41, where the cardinal symptoms of acute intestinal obstruction are enumerated, pain is not mentioned, though on p. 65 it is just discussed. Persistent vomiting is stressed as a most important symptom; but in large intestine obstruction vomiting does not come on for at least 48 hours, and the diagnosis by enema results is now recognised as unreliable. These two conditions—acute osteomyelitis and acute obstruction—have been singled out for criticism because the patient's chances of recovery depend to so small a degree on the technical skill of the surgeon's carpentry, and almost entirely on his skill as a diagnostician, and the advice concerning the diagnosis of these conditions seems rather to perpetuate old fallacies than to offer the lessons of modern practice.

The serious need for the better education of the operating general practitioner in the country is undoubted, and books of this type should exert a widespread influence—for Mr. Howard's is a good book, though we have considered it right to make certain criticisms. For it is even more important that the advice given here should be up to date than in text-books for the surgeon-consultant, who has ample opportunities of discussing technique with his fellows. In many respects, as we have noted, Mr. Howard's book is an excellent guide, and will doubtless be of real service to surgeons in general practice.

HEALTH BUILDING AND LIFE EXTENSION.

A Discussion of the Means by which the Health Span, the Work Span, and the Life Span of Man can be Extended. By EUGENE L. FISK, M.D., Medical Director, Life Extension Institute of New York. New York: Macmillan Company. 1923. Pp. 521. 16*s*.

THE work of the Life Extension Institute of New York is becoming increasingly appreciated by medical men; and this volume attempts a philosophical review of the factors of individual hygiene, of industrial hygiene, and of public health, in their relative importance, and of the possibilities of measures for reducing the tax of sickness on life. The scheme of the book is clear. Part I. deals with the physical state and the extent of disabling sickness, the possibility of reducing this, and of extending the cycles of life, of health, and of work, and the value of periodic examinations and health supervision. Part II., whose contents fall under the general heading of industrial health and working capacity, gives a review of poisons, of food deficiency and excess, psychical influences, and, indeed, of nearly all the known enemies to health; while in Part III., federal, state, community, and industrial health organisations are outlined and a special chapter is devoted to "drives" against individual diseases.

The volume contains a vast mass of information, clearly stated, and most useful and stimulating to the reader who can distinguish between facts of small and of great importance, and between inferences of greater and less degrees of probability; no physician or medical officer of health can read it without receiving useful stimuli to a wider outlook on the problems of his professional life. In the earlier part of the book there is an elaborate statistical discussion of the increasing mortality in the United States at higher adult ages, and on the increasing mortality from some degenerative diseases, the statistical basis of which is not above suspicion. But the main fact remains that such diseases are excessive, and might be decreased; though it may be doubted whether experimental results with animal tissues justify the "philosophical validity of the postulate that human life may be indefinitely extended." The illustrations of possible savings from periodic examination and health supervision in university life are striking, and it is certain that increasing use of this means of diminishing sickness is advisable; but examination and supervision in adult life do not cover the major problems, for, as is urged by Sir A. Newsholme in his Harveian Lecture (January, 1921), "the chief and most promising line of attack on the disabling diseases of middle life and even of higher ages consists in the adoption of all known preventive and curative medical measures in childhood and in youth, adolescence, and early manhood. It is chiefly in these years that the bill is incurred which has to be paid two, three, or four decades later." The truth of this statement is evident when we recall the rôle of various infections, and especially of the virus of rheumatic fever and o syphilis in causing arterial and other diseases.

The sketch of official health agencies in the Unite States is most instructive, and should be consulte by British readers. There is sound sense in th comment on medical education as still commonl conducted, that students have as their ideal th treatment of disease rather than the maintenanc of health. A great deal is said to them about preven tive medicine, but they visualise it chiefly as sani tation and community hygiene. Personal hygien is seldom adequately taught. The suggestions o mutual benefit and group insurance are also worthy o careful study. In the United States action is pro ceeding largely on the basis of individual industries with us it is progressing on commercial lines. I the chapter on special drives against disease attentio may be drawn to the excellent discussion of th venereal disease problem. The value of the volum is increased by the admirable bibliography attache to each of its three parts.

COMMON INFECTIONS OF THE FEMALE URETHRA AN CERVIX.

By FRANK KIDD and A. MALCOLM SIMPSO London: Humphrey Milford, Oxford Universit Press. 1924. Pp. 191. 7*s*. 6*d*.

THIS book is a description of the cases investigat by the authors in the female V.D. department the London Hospital from January, 1917, till la 1920; 650 cases in all appear to have been see of which 237 only were gonococcal cases; 50 childr came in the series, and 21 of the patients we pregnant and also infected with gonorrhœa. T numbers investigated therefore were not large.

It is an interesting book, somewhat unequal quality. In the field which Mr. Kidd has made own he is unsurpassed. Therefore the section examination of the urethra and the treatment of urethritis and of bladder infections is excellent, and will be of the greatest value to general practitioners, for whom the book seems to be intended. As an addition to the literature of gonorrhœa in women it must be taken less seriously—the number of cases seen is too small, and according to present ideas the cures are too easily come by. Everyone working with infected women in large numbers knows that with modern technique negative films and cultures are obtained in a subacute case in a short time; but it is also a well-recognised fact that relapses—not always due to reinfection, as Mr. Kidd seems to believe—are frequent. No after-history is given of any one of the 21 pregnant cases "cured before parturition" (p. 81), and there is no note as to the clinical or pathological condition a month or six weeks after delivery, which is regarded by many observers as the real test of cure in such cases.

A note on primary syphilis of the cervix gives rise to some doubt as to the amount of treatment the authors consider necessary (pp. 74 and 75): "the primary stage, when abortive treatment by salvarsan is possible" might be taken to indicate that the authors think one or two injections of salvarsan will completely rid the patient of syphilis. We feel sure that the last thing that the authors intend is to encourage half-hearted treatment of syphilis, which certainly causes the lesion to heal, but inevitably leads to relapses later and to the birth of infected children. There is an interesting section on treatment of gonococcal arthritis in which the authors rightly deprecate undue or unskilful massage and insist on the value of movements by the patient. An admirable chapter on the bacteriology of the region by Dr. Western, and another on ophthalmia neonatorum by Mr. Mayou, add to the value of the book; and a chapter on prophylaxis against V.D. will be of use to many practitioners. A few very good colour plates are included.

PSYCHIATRY.

Mental Diseases. A Text-book of Psychiatry for Medical Students and Practitioners. Third edition. By R. H. COLE, M.D. Lond., F.R.C.P., Physician for Mental Diseases to St. Mary's Hospital. London University Press. 1924. Pp. 356. 15*s.*

Insanity in Everyday Practice. By the late E. G. YOUNGER, M.D., M.R.C.P. Fifth edition, revised and edited by G. W. SMITH, O.B.E., M.B., Ch.B. London: Baillière, Tindall and Cox. 1924. Pp. 134. 5*s.*

CERTAIN changes have been made in the new edition of Dr. Cole's text-book. The principal alterations are a much elaborated chapter on the pathology of general paralysis, a rewritten description of the cerebro-spinal fluid, and a new section on the anxiety neurosis. The value of the book from the point of view of the student, for whom it is primarily intended, depends chiefly on the excellent descriptions of the clinical features of insanity, and in these no changes have been made. Although minor additions have been made in the chapter on treatment, a short paragraph reflecting the somewhat nebulous outlook of 20 years ago remains the only reference to the vaccine and other specific treatment of chronic septic states, and the possible influence of focal sepsis, and the importance of searching for it, are barely mentioned. Although such knowledge is, perhaps, not essential for examination purposes, it is surely of use to impress on the student that a bodily cause for mental derangement should always be sought for, and that a better understanding of immunology may eventually remove certain types of insanity from those large categories in which ætiology is still conjectural and treatment merely expectant. This omission detracts hardly at all from the value of an excellent manual, and we note it only because a dogmatic enumeration of the stereotyped factors in ætiology, with no adequate confession of our gross ignorance, and no hint as to the lines along which progress is likely to be made, must be apt to produce in the reader an attitude of passive acquiescence in a mystery, from which we must escape if psychiatry is to be advanced.

The late Dr. Younger's short manual on Insanity in Everyday Practice has been revised by Dr. G. W. Smith, his aim having been to bring it into accordance with more recent views of mental disease without altering its general purpose or character. The original author's intimate and readable description of the outward features of insanity are combined with much practical advice as to the immediate steps to be taken in dealing with various types of patient, and warnings as to pitfalls in the difficult situations which cases of mental disorder in general practice may provide. Actual experience of mental hospital work, however brief, can alone arm the practitioner adequately against these difficulties, but in so far as mere reading can be of service, this small volume will be found one of the most helpful of its kind.

VERTEBRATE ANIMALS.

A Manual of Land and Fresh-Water Vertebrate Animals of the United States (Exclusive of Birds). By HENRY SHERRING PRATT, Professor of Biology in Haverford College, Pa. Philadelphia: P. Blakiston's Sons and Co. Pp. 422.

THIS work deals with the Fishes, Amphibians, Reptiles, and Mammals of the United States and Southern Canada. It has been written to furnish students of zoology and geographical distribution with diagnostic descriptions of the land and fresh-water vertebrate animals of that part of the world, and numerous analytical keys are given by which the animals can be identified. To an extent it is a compilation of many other works dealing with special groups, and a full bibliography of the works referred to is given. It is well illustrated and all the illustrations have a bearing on the diagnostic points referred to in the text. In the section dealing with mammals, the splitting up of the various members of the family Muridæ into species and subspecies seems to have been carried to excess, but it speaks well of the thorough way in which the local races have been worked out by American zoologists. It is a book which should prove a valuable help to collectors and systematists on the particular branch of zoology with which it deals.

PATHOLOGISCH-PHYSIOLOGISCHE PROPÄDEUTIK.

Von MAX BÜRGER, A.O. Professor der Inneren Medizin und Oberarzt an der Med. Universitätsklinik, Kiel. Berlin: Julius Springer. 1924. S. 342. $2.90.

THIS book may be regarded as the type of the pathological text-book of the future. It contains no horrifying pictures of monstrous births nor lengthy descriptions of "histological appearances." The author has written from the standpoint that pathology is morbid physiology; this being the case, he has abandoned the static outlook of the old-time pathologist for the dynamic attitude of the physiologist. Such a book could hardly have been written until within the last few years. The General Pathology, edited by Pembrey and Ritchie, and published in this country in 1913 (of which a further edition is long overdue), was the first, and heretofore almost the only, work of the sort. Comparison of the two books is cheering in the indications provided of real advance in the knowledge of morbid processes within the last ten years. Prof. Bürger has been ambitious in his aim; all the systems of the organism are dealt with, and always from the standpoint of function. For the reader brought up on things in bottles or slices of tissue on bits of glass it will be difficult going; all of it is not, perhaps, entirely profitable, and much of it will have to be recast in the near future. None the less, there can be no doubt as to the high value of works of this sort in opening the way to a proper understanding of the processes underlying disease. An hour's intelligent study of this volume should do more to lead to such an understanding than weeks of grinding at the histology of tumours. Practically all the references are to German publications. A wider outlook would have prevented the appearance of such anachronisms as the inclusion of the virus of yellow fever among the unidentified filter-passers.

THE APOTHECARIES' GARDEN AT CHELSEA.
Second edition, revised and enlarged. By F. DAWTREY DREWITT. London: Chapman and Dodd, Ltd. Pp. 136. 5*s.*

IN a second edition Dr. Drewitt has revised and enlarged his charming little romance of the "physic garden" at Chelsea, the additional notes on Linnæus being particularly interesting. We reviewed the first edition at length recently (THE LANCET, Jan. 20th, 1923), so that no full notice of the work will be required by our readers, whom we again recommend to make themselves acquainted with the story of this small oasis in the brick desert of London. The closing chapter on the trees to be found in the Apothecaries' Garden should open the eyes of Londoners to the variety of trees which are to be found, not only by going to the Garden, but by strolling in the metropolis; trees may be there seen which are generally associated with the narratives of distant travel. The suggested origin of the yew tree in our churchyards is interesting as showing that 2000 years ago contractors would use substitutes when they could do so with impunity.

JOURNALS.

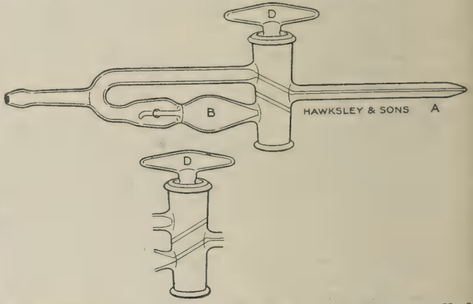
JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXVII., No. 2. Pp. 145–215. April, 1924.—The Constituents of Serum Useful in the Cultivation of the Gonococcus, by C. E. Jenkins (Salford). Blood is helpful chiefly in primary cultures and early subcultures; serum or plasma contains the needful substances, one of which, peculiar to blood, is destroyed by heating to 65° C., while the other, found also in muscle, resists heat up to 100° C. A convenient plan of sterilising slaughter-house serum by warming with acid and chloroform is described.—The Hæmophilic Bacteria of the Normal Throat, by J. H. Dible (Manchester). Examination of the throats of 100 normal persons revealed bacteria which required hæmoglobin in the medium in 47 cases. Critical examination showed that in 30 of these the organism corresponded with Pfeiffer's influenza bacillus. In 20 cases other hæmophilic organisms were present, most of which were hæmolytic.—Acid-fast Bacteria as a Source of Vitamin B, by S. R. Damon (Baltimore). A growth-stimulating substance analogous to vitamin B is produced by the timothy grass, Möller's and the smegma bacillus.—Compensatory Hypertrophy of the Suprarenals, by A. E. Boycott and C. H. Kellaway (London). Removal of one adrenal in young rabbits does not lead to compensatory hypertrophy of the other gland.—Non-specific Training of Anti-Body Production, by V. R. Khanolkar (London). Preliminary doses of Gaertner's bacillus increase an animal's capacity to produce agglutinins to that organism: so do preliminary doses of *B. coli*, paratyphoid B, *B. pyocyaneus*, and sodium cinnamate. But injections of staphylococci, ricin, horse serum, or yeast do not have this effect.—The Titration of Diphtheria Toxin and Antitoxin by Flocculation Methods, by A. T. Glenny and C. C. Okell (London). When people began to look carefully at what they were doing, they found that mixtures of diphtheria toxin and antitoxin are opalescent or flocculate at the point corresponding to neutrality by the usual animal test. The method, which has been exploited particularly by Ramon, has the advantage of giving quick results and of being economical. With most ordinary toxins the values found correspond with those given by subcutaneous or intracutaneous guinea-pig tests, but this is not always the case. The process, therefore, cannot replace the classical direct methods.—The Pathology of Iron Deficiency and Cotton-seed Poisoning in Pigs, by J. P. McGowan (Aberdeen).—Metastatic Carcinoma of the Pituitary Gland with Diabetes Insipidus, by A. Piney and I. Coates (London). A secondary growth from a breast cancer completely destroyed the partes posterior and intermedia of the pituitary; there was great polyuria. The pars anterior remained intact, and the case strongly supports the view that the polyuria of pituitary origin comes from the unopposed action of this portion of the gland.

Messrs. Baillière, Tindall and Cox inform us that the new edition of "Aids to Physiology," reviewed in our columns on Feb. 9th (p. 290), should have appeared under the sole authorship of Dr. R. A. Krause, for although Prof. J. Tait wrote the previous edition in collaboration with him, Dr. Krause is entirely responsible for this.

New Inventions.

AN AUTOMATIC PIPETTE FOR HÆMATOLOGICAL PURPOSES.

THE great difficulty of attaining accuracy in counting blood corpuscles has probably been encountered by all laboratory workers and the pipette which is here illustrated serves to obviate personal errors. The chamber B serves for the reception of the diluting fluid, which is sucked up to fill that chamber; any excess passes through the fine capillary and is trapped in the further chamber. The tap D is now turned into the position shown in the upper illustration and the excessive diluting fluid contained in the stem A can be expelled by blowing through it. The stem is then cleaned with alcohol and ether in the ordinary way. Blood is now sucked into the stem A and through the bore of the tap. If the tap be now turned through an angle of 45° the blood in the stem is cut off. The tap is then turned through an angle of 45° and the chamber B is brought into communication with the blood when the two fluids can be expelled into a suitable small vessel and shaken. The apparatus is available for red corpuscles, leucocytes, and hæmoglobin. In the case of red corpuscles the chamber B plus the tap contain 100 parts of diluting fluid while the stem contains one part of blood. In the case of the leucocytes the figures are 10 and 1 respectively. The pipette for measuring 20 c.mm. of blood for the estimation of hæmoglobin is similar but simply possesses a plain U-tube above the tap. Cleaning of the apparatus is carried out by placing the rubber tube of the mouth-piece on the end of the stem A and sucking in and expelling distilled water, &c. The pipette, I think, avoids the difficulties which were associated with the Hirschfeld model, though somewhat resemblng that instrument.



The pipette has been made for me by Messrs. Hawksley and Sons, of Wigmore-street, London, W.

A. PINEY, M.B., Ch.B.Birm., M.R.C.P.,
Director of the Institute of Pathology, Charing Cross Hospital.

THE LANCET.

LONDON: SATURDAY, MAY 3, 1924.

MYOPIA AND THE CHOICE OF A CAREER.

THE report of the Council of British Ophthalmologists, published in the *British Journal of Ophthalmology* for April and reproduced in another column, is of the first importance. It is mainly concerned with the question how far myopia should be treated as a disqualification for candidates for scholarships and teacherships under local educational authorities, but it may also be taken as an authoritative guide in assisting parents to decide on a career for short-sighted children. The most important recommendations are as follows :—

> "A child of 11 with three or more dioptres of myopia in the better eye should be rejected for scholarship training.
>
> At the age of 15 those with more than four dioptres of myopia in the better eye should be deemed unfit to train for the teaching profession.
>
> Candidates for entry into training colleges, who are, as a rule, about 18 years of age, if they have more than five dioptres of myopia in the better eye should be rejected."

These recommendations are calculated to cause a good deal of heart-burning both among parents and among clever children who, though they are short-sighted without spectacles, see normally with them and have never had any trouble with their eyes. Myopic children, in fact, are very apt to be bookworms, and while it may be difficult to say which is cause and which effect, the association is an instance of a vicious circle. The fact remains that many of these children, from all points of view except that of their eyesight, would seem peculiarly fitted both for scholarships and for the teaching profession.

What, then, is the justification for these recommendations ? It is to be found in the following facts : (1) That in later life cases of weak sight are found to occur in those with myopia and myopic astigmatism in far greater proportion than in any other state of refraction ; (2) that this condition is not congenital, but is apt to become more pronounced during the years of adolescence, especially in children and adolescents who are unusually studious. It is perfectly true that there are a large number of myopes, of even moderately high degree, who seem to suffer no inconvenience and whose eyes do not give out even in later life under the stress of employment involving continuous close work. In legislating, however, we must have regard to the greatest good of the greatest number, and though it may be perfectly true that there are many myopes, even of comparatively high degree, who would benefit both themselves and the community by taking up studious careers, and would suffer neither inconvenience nor even partial loss of sight later on, unfortunately in early life we have no means of separating these from the others of whom the opposite is true. In order that the authorities, and parents themselves, may realise how great is the risk in encouraging these myopic children to train themselves for employments involving continuous close work, we commend the careful study of some figures published a few years ago by Mr. BISHOP HARMAN.[1] From his private case-books, he tells us, he picked out all those myopes of over 3 D. who were between the ages of 20 and 60 years, cases of monocular myopia being excluded. The total number of myopes thus collected was 480. The cases were separated into two main sections : (1) Habitual close workers, and (2) those not so engaged. In each section there was an age-grouping in decades, and also in groups, according to the grade of their myopia—from 3 to 5 D., 5 to 10 D., and over 10 D. In cases of astigmatism the average of the four meridians was taken as the degree of myopia. Note was made of the events of their working history, the occurrence of indications of abnormal stress in work, breakdowns which entailed cessation of work, or change of work where that was possible, or a continuance of the same work under modified conditions ; and lastly, of direct evidence of damage to the eyes. Of the 480 cases investigated, 38 per cent. were engaged in habitual close eye work, and 62 per cent. were not occupied in continuous close eye work. The extent of the failure amongst the habitual close eye workers as compared with the other patients was remarkable. No less than 53 per cent. of the close workers failed at some time during their career, and of these more than one-quarter, or 15 per cent., of the total of habitual close workers sustained permanent damage to the eyesight. Amongst the myopes who were not close workers failures were few—only a total of 9·4 per cent. The fact that the majority of these (7 per cent.) sustained damage to their eyes is accounted for by the comparatively large proportion of very high myopes in this group.

Mr. HARMAN'S tables show not only the above comparison, but also that there is a gradual increase in breakdowns and damage to the eyes with the increase of age and grade of myopia. Amongst the ordinary patients there was only one case of trouble at any age amongst those with less than 5 D., but quite a number amongst the habitual close eye workers (out of 71 cases, 21 breakdowns and 3 cases of damaged sight). In the cases of myopia from 5 D. to 10 D. the figures are far more striking. Of 81 habitual close workers, no less than 40 had had breakdowns in their work and 9 had sustained permanent damage to the sight ; whilst of 118 not engaged in close work there were only 3 breakdowns and 4 cases of damaged sight. In the cases of myopia of still higher grade the figures are less comparable owing, on the one hand, to the fact that the myopia in many of these cases must have developed in comparatively early childhood and served as a warning against any employment trying to the eyes, and on the other hand, to the much enhanced risk of damaged sight in these cases, irrespective of whatever precautions are taken. These facts, as it seems to us, afford ample justification for the recommendations of the Council of British Ophthalmologists. They are in consonance with what we may term the orthodox teaching as to the dangers of close work for myopes, and although some recent authorities have attempted to throw doubt on this teaching we cannot evade the conclusion that the verdict contained in the report—which proceeds from the leaders of the ophthalmic branch of the medical profession in this country—is sound.

SCHOOL CLOSURE FOR INFECTIOUS DISEASE.

From time to time the parents of children away at boarding schools are agitated by the intimation that infectious disease has occurred at the school, and that in consequence the school will be closed before the date on which the term should end. No doubt in individual and exceptional instances such a precaution as school closure may prove to be the smaller of two evils. We doubt, however, whether the occasions for its application are nearly as frequent as headmasters, through their own anxiety or through the cautious counsels of their medical advisers, would lead us to believe.

The experience of the school medical service of this country appears steadily to be crystallising in a form opposed to the use of school closure as an instrument for the control of infectious disease. The arguments which apply to the procedure in its relation to the public elementary schools, both urban and rural, in this country seem to have special point in respect of boarding schools. The closure of the school involves a general dispersal of the occupants to families or communities, in many of which they will not be under any degree of careful supervision; the one original focus of infection may thus multiply itself in a number of different localities. Had the school been kept open, and had the daily medical and nursing supervision been adequate, each fresh case as it arose could, in most of the infectious diseases, have been detected at a stage before infectiousness had developed to a material degree. Moreover—and this is an aspect which appeals to the long-suffering parent, though he accepts the prevailing practice with singularly little grumbling—the child would receive the term's schooling contracted for and paid for, but only in part received under conditions of premature closure. Undoubtedly the present practice is based, not on closure as a true means of controlling infectious disease, but on the lack of pains taken in many boarding schools to evolve an effective machinery for the daily supervision of the health of the pupils. The happy-go-lucky attitude which enters so much into the spirit of the recreations of the boarding school permeates the attitude of the principal and of the staff towards the physical health of the inmates. Probably quite a small proportion of the masters have any knowledge of the symptoms and signs of infectious disease approaching that acquired by the elementary school teacher, while the school nurse, with a thorough grounding in infectious disease, who is so closely linked up with the public elementary school, is, on the whole, distinctly more expert in this subject than is the average matron at a boarding school. We believe that some degree of concentration on this aspect of the control of infectious disease in residential schools would result in a material drop in the frequency of premature closure.

But while the experience of school medical officers in the service of local authorities is in general increasingly unfavourable to closure as a preventive measure against the spread of disease, it must be confessed that their practice does not always march with their precept. It is not uncommon for school medical officers to advise closure of an elementary school department on account of infectious disease when the attendance drops to a low level—perhaps in the neighbourhood of 50 per cent. of the normal—such closure being largely for the convenience of the education authority, and to save loss of grant from the Treasury on account of low attendance rather than because the medical officer has any faith in closure as a means of controlling the outbreak. It needs something of the casuist to draw any clear distinction between the school medical officer acting on such a basis and the headmaster of a boarding school who closes his school on account of infectious disease. Is there not scope for both to review their methods and to define the procedure which will make for the greatest good of the children under their supervision?

◆

TUBERCULOSIS OF THE LARYNX.

The Medical Research Council has just published[1] an instructive account by Sir StClair Thomson of his experience of laryngeal tuberculosis at the King Edward VII. Sanatorium at Midhurst over a period of ten years. During this period 2541 cases of pulmonary tuberculosis were admitted, and among them were 477 cases of tuberculous invasion of the larynx. The author adopted the happy method of passing all his case-cards and notes to an independent worker, Dr. D. A. Hutcheson, who compiled the figures, tables, and averages without any suggestion from anyone as to the conclusions which might be anticipated, thus avoiding to a very great extent the personal bias inevitable in all human undertakings. The conclusions to be drawn from the statistics thus analysed do not, as a whole, differ greatly from the many similar figures which have previously been compiled. In one respect, however, there is a marked difference; while numerous tables compiled up to ten years ago show that laryngeal invasion was two to three times more common in men than in women, the Midhurst figures make the incidence almost exactly equal. Sir StClair Thomson points out that most of the women admitted to Midhurst are wage-earners who follow the same, or similar, employments as the men—viz., clerks, typists, teachers, &c.—and concludes that any increased susceptibility of the male is due to social, and not to sexual, differences. Before 1905 the post-mortem records at the Brompton Hospital showed twice as many cases of tuberculous laryngitis in men as in women, but since 1908 the proportion has been almost identical; the question arises, is this the result of the change of habits and occupation among women? For the last five years of this investigation, involving 1456 patients, notes were made of the condition of the nares and pharynx; the conclusion is that affections of this region are no more common in those with laryngeal invasion than in those whose disease is limited to the lungs; also, though it would be difficult to make a comparison of the nose and pharynx in sanatorium patients with an equal number of the healthy public, the author's impression is that trouble in these regions is no more common in a sanatorium than out of it. Three cases of intrinsic cancer in phthisical patients provide interesting examples of the difficulty of differential diagnosis. The author concludes that epithelioma of a vocal cord is a very slow-growing tumour; if it is so limited as to be difficult to recognise, a delay of two or three months in clearing up the diagnosis can do little harm. There is also a unique case of aspergillosis of the lungs and larynx, the latter presenting a typical picture of tuberculosis; recovery was rapid under sanatorium treatment.

So much for the pathology of laryngeal tuberculosis. The chief feature, and the great value, of Sir StClair Thomson's report lies in the emphasis laid on the remarkable benefit which the tuberculous larynx derives from sanatorium régime, including good air, regular rest, diminution of voice use, control of cough, and cessation of alcohol and tobacco. The tuberculous larynx, as seen in a clinic among town-dwellers, is usually in a condition of general congestion, which makes it difficult to distinguish the deposits of disease, angry granulations being bathed in abundant pus. All this subsides in sanatorium without local treatment, and it soon becomes evident that 20 to 50 per cent. of the unhealthy appearances were added conditions, the result of hygienic unrighteousness. Practically all the laryngeal cases at Midhurst were "put on whispers"; the patient is told to speak only on the lips, and is warned against using a forced whisper or speaking at all out of doors or at table. Of the 477 laryngeal cases, 336 had no other special treatment, and of these 50 cases were cured. Complete silence, with the use of writing block and pencil, is rightly recognised to be a severe measure; it was reserved for recent and acute cases, especially of the glottic margin, and only for such as offered a fair prospect of cure; it was seldom prescribed for a longer period than six months, for if the condition did not clear up within that time it was recognised as unpromising and put on to "whispers" or, in some cases, treated by the galvano-cautery. Silence was prescribed for 67 patients, of whom 23 were cured. The only active method of local treatment employed was galvano-cautery puncture; this was used when the general conditions were favourable and the spontaneous healing, after making progress, appeared to be slow or stationary. Local anæsthesia and the "indirect" method were always employed, two to six punctures were made at a sitting, and never more often than once a month. In all, 74 cases were considered suitable for this method of treatment, and of these a cure was obtained in 46. Thus of the 477 cases of laryngeal tuberculosis, 119 (24·9 per cent.) were cured, 73 by restriction of voice use, and 46 by cautery puncture, in addition to the sanatorium régime. This is, as Sir StClair Thomson remarks, a result which is very encouraging, when compared with Sir Morell Mackenzie's statement of 50 years ago that "of all the cases that I have ever seen, I only know of four in which I have reason to believe that the disease was entirely arrested." The direction in which further progress can be made lies chiefly in earlier diagnosis and more prompt resort to sanatorium, and especially in a general recognition of the fact that persistent hoarseness requires expert investigation. A comment upon a sentence in a recent annotation in our columns is curious, for this report lays stress on the difference between present-day methods and results when compared with the narrow outlook and hopeless results of a generation ago.

◆

AN IMPROVED ACETONE-PICRATE PROCESS FOR INSULIN.

Certain modifications of the acetone-picrate process for the preparation of insulin, described by Dr. E. C. Dodds and Dr. F. Dickens in The Lancet of Feb. 16th, 1924, p. 330, have been published by these authors in the April number of the *British Journal of Experimental Pathology*. That watery extracts of the pancreas could yield active material was known from the beginning of work on insulin, since Banting and Best's original method consisted in a watery extraction of pancreas, and the first preparation of active substance was obtained in this manner. When tried on a large scale, however, the yield was so poor as compared with the alcohol extraction process that the method had to be abandoned. Best and Scott state that out of some hundred experiments their best yield obtained by aqueous extraction was only a quarter of that obtained by their alcohol process. Two causes of difficulty arise: (1) The inhibition of tryptic action; (2) efficient separation of insulin from the relatively enormous mass of protein. The authors state that the first cause of loss was reduced, and the second difficulty completely overcome, by the method described by them in our columns. Summarised briefly, the method consisted in extracting the pancreas with 1 per cent. formic acid, and precipitating the proteins and insulin from the resulting solution by means of picric acid. The picrates were then extracted with acetone. This separates the insulin picrate from the proteins, the acetone dissolving out the former and leaving the latter undissolved. The acetone solution was then diluted with equal volumes of saturated aqueous picric acid and water, when the insulin picrate separated. This was collected, washed, and converted to the hydrochloride by Dudley's method. The average yield by this method was in the neighbourhood of 300 rabbit-units per kilo of pancreas. This process was found to be difficult on a large scale owing to the time expended on the separation of the solid pancreatic tissue in the first stage. Also, in view of later experiments, it became obvious that about 40 per cent. of the yield was lost by the incomplete precipitation of the picrate by dilution. In order to improve the process it was necessary (1) to include some powerful tryptic inhibition to the extracting substance; (2) to adopt the removal of the acetone by distillation, before precipitating the picrate. Many substances are known to inhibit the action of trypsin, but the majority also act upon insulin and impair its activity. Paraldehyde is free from this objection, and its addition was found to be advantageous. The modified method differs from that described in The Lancet only in the addition of 5 per cent. of paraldehyde to the extracting fluid. Although paraldehyde is immiscible with water in this proportion, an emulsion is formed on mincing with the pancreas. The result of a typical experiment was a yield of 535 rabbit-units per kilo, as compared with 300 by the original process. As to distillation, some investigations on the properties of the picrate have shown the incompleteness of the precipitation from acetone solution obtained by the dilution method. It was thus clear that an increased yield should be obtained as a result of distilling off the acetone. This procedure was adopted with good results, and the next step was to combine both of these modifications, and this was done, the yield of a typical experiment being equivalent to 1040 rabbit-units from 1 kilo of pancreas. Although the results obtained by this process were consistently good, and the time factor was reduced to two days, there was still the objection that the first filtration was troublesome on a large scale, owing to the gelatinous nature of the material. In view of the ready solubility of insulin picrate in 70 per cent. acetone and the insolubility of protein picrates, it was an important point to ascertain whether this preliminary aqueous extraction of the pancreas was necessary, and whether picrates could not be prepared simply by grinding pancreas with solid picric acid. The application of picric acid to the original tissue, as a step in the extraction of insulin, was discussed by the authors with Dr. H. W. Dudley, who informed them that it was already under trial by him for fish islets. After a series of experiments on these lines, the authors evolved a method, of which full details are given in the article, whereby the average yield of hydrochloride was equivalent to about 1000 rabbit-units from 1 kg. of pancreas, and had a rabbit-unit of 0·5 to 1 mg. In one experiment (Experiment 24), in which 8 kilos of pig pancreas were worked up by this method, the high yield of 3·690 g. was obtained, the rabbit-unit of which was 0·25 mg., thus giving a total yield of 14,760 rabbit-units, or 1845 rabbit-units per kg. of pancreas. So far as the authors know, this is the highest yield of insulin recorded. The authors' comments on the method are as follows: 1. The use of solid picric acid not only renders the first tedious filtration unnecessary, but by converting the insulin directly to picrate reduces the time during which tryptic action may occur to a minimum, thus increasing the yield. 2. By centrifuging the acid-alcohol solution of the picrate in the last stage a large quantity of insoluble material is removed. This consists of protein insoluble in 75 per cent. alcohol, and is quite inactive physiologically. It probably consists of part of the fraction which is precipitated at an earlier stage in the Collip process. The removal of protein in this way gives a product of a very high degree of purity. 3. The rabbit-unit of the "crude hydrochloride" is in the neighbourhood of 0·5 mg., which is as low as that of the purified insulin made by the Collip process and subsequently purified by Dudley's method. 4. The time of the complete process is about one day. Small batches of up to 10 kilos have been worked up within six hours. 5. The process presents no difficulties with regard to filtration, as all the precipitates are very easily handled. The rabbit-units given in this paper are in terms of the original Toronto units—viz., the quantity required to lower the blood-sugar of a 2-kilo rabbit to 0·045 per cent. within two hours.

◆

HOSPITAL PROBLEMS.

The serious attention given to different aspects of the hospital problem at the conference reported on p. 923 is timely in view of signs that the provision of hospital beds throughout the country is inadequate to the needs of an increasing population, and of the financial difficulties which alone prevent voluntary hospitals from enlarging size and scope. We note in our news columns (1) that Mr. Wheatley (*v. infra*) has requested the Voluntary Hospitals Commission to inquire into and to report upon the extent of the additional voluntary hospital accommodation required in England and Wales, and the best means of providing and maintaining it; and (2) that in the Manchester and Salford districts, for example, it is computed that there are nearly two cases waiting for each of the 2444 voluntary hospital beds available. The fact that beds in infirmaries (when this word is used in the sense of hospitals under the Poor-law) could be utilised at need to supplement the voluntary hospital beds is recognised, but there is general agreement that the public will not avail themselves of such facilities under the present system of administration. There is much in common between the ideals set out by the Labour Party for the provision of a health and hospital service and the principles which have long guided those who are responsible for administration of voluntary hospitals. The admiration for the voluntary system expressed by prominent Labour leaders is sincere, and there is no reason why the coördination and coöperation for which they plead should necessarily lead to its extinction. Such conferences as that just held should be fruitful of a better understanding between those sections of the community which have as a common aim the maintenance of an efficient health and hospital service throughout the country.

Voluntary Hospitals Commission.—In reply to a recent question in the House of Commons regarding the number of persons requiring hospital treatment but unable to obtain it through lack of beds, the Minister of Health indicated that he proposed to ask the Voluntary Hospitals Commission to undertake an inquiry into the shortage of hospital accommodation. Mr. Wheatley has now remitted this question to the Commission with the following terms of reference: "The Voluntary Hospitals Commission are requested to inquire into and to report upon the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it." The Commission will be communicating immediately with the Local Voluntary Hospital Committees in regard to the steps to be taken in pursuing the investigation, and the matter will also be the principal subject of discussion at the conference of representatives of the Local Voluntary Hospital Committees, which is to be held on June 18th at the Ministry of Health. It is understood that a separate inquiry will be undertaken in regard to hospital accommodation in Scotland.

Annotations.

"Ne quid nimis."

IMPERIAL SOCIAL HYGIENE CONGRESS.

This Congress, as has been already announced, has been organised by the National Council for Combating Venereal Diseases, and sits at Wembley, during the British Empire Exhibition, from May 12th to 16th. The Medical Section sits on Thursday, May 15th, with Mr. E. B. Turner as President, and as the majority of medical practitioners will be unable to spare time to attend the whole Congress, a special arrangement has been made for day tickets for this section. These can be obtained from Miss E. O. Grant, Secretary, N.C.C.V.D., 102, Dean-street, London, W. 1, at a cost of 5*s.*, this sum including entrance to the grounds. In the morning there will be a special display, for medical practitioners only, of the medical film, the Diagnosis and Treatment of Gonorrhœa in the Male. This has been produced for the N.C.C.V.D. under the direction of Colonel L. W. Harrison, who will be present to explain the film. In the afternoon, from 2.30–5, there will be a conference on the "Position of the General Practitioner in Anti-Venereal Disease Schemes." Papers are being contributed by Dr. C. E. S. Flemming, Dr. Madeleine Archibald, and Dr. Alfred Cox, and others will take part in the discussion afterwards, which will be thrown open for participation to any member of the audience.

ENDOTHELIUM AND ANTIBODIES.

Scientific literature is at times apt to be a little monotonous in form if not in substance. Eruditus makes certain observations or experiments from which he deduces a certain conclusion. And if the substance as well as form are conventionally beyond reproach, the communication may still be rather like Johnson's dictionary—very interesting, but the least thing deficient in plot. It is therefore quite refreshing to find in the *Journal of Hygiene* (Vol. XXIII., p. 355) a paper by Dr. A. Eastwood, of the Ministry of Health, of a purely speculative character which seeks to do what is so much needed nowadays to put together some of the superabundance of facts into a new and coherent general notion. Antibodies are generally assumed, perhaps as much for convenience of discussion as for an expression of absolute truth, to be "somethings" which are produced by the body in response to the stimulation of a foreign protein, the antigen. Whether these "somethings" are new proteins or old proteins impressed with new properties is relatively immaterial. As a working hypothesis it has also been fruitfully assumed that the antibodies in some way fit the antigens, giving the characteristic and apparently qualitative specificity. Dr. Eastwood rightly points out that the foundation for all this is nebulous, though he does not, perhaps, attach sufficient weight to the physiological phenomena, the influence, for example, which practice and experience has on an animal's capacity to "produce antibodies." He then points out that no one organ in the body can be regarded as the generator and source of antibodies, but that a variety of evidence indicates that they may be produced anywhere—which, with any faith in the connexion between structure and function, leads to the guess that either connective tissue or endothelium has a good deal to do with it. From this he develops the conception that what we call antibodies are normal body constituents which have been altered by passing through the endothelium separating tissue fluid from blood, and that what the antigen does is not to stimulate some tissue to do something, but to alter the endothelium so that the fluids passing through are modified to some extent in a specific way. He regards "antibodies" as a living mechanism in the circulating plasma rather than as molecules of particular chemical configurations, and he rightly objects to the assumption that the test-tube phenomena of the serologist represent adequately the properties of live plasma. For a full presentation of his ideas the original memoir must be consulted. It should, however, be added that Dr. Eastwood is fully alive to the difficulties in the way of his interesting and suggestive hypotheses. On the particular point of endothelial filtrates he might, perhaps, have added more. While most of the antibodies (sensu serologico) of an immunised animal are in the blood, bleeding and the subsequent restoration of the blood volume by the taking up of tissue fluid from outside the vessels does not decrease their concentration for any length of time. Inconclusive as they are, these observations long since suggested that antibodies arose in some way during the passage of liquid from the tissue spaces into the blood.

A PROPHYLACTIC HUT.

This week-end Sir Henry Gauvain is opening the "Howard Marsh Hut" at St. Andrew's Home, Hayling Island, which has been presented to the Brompton Hospital by Mrs. Marsh in memory of her husband. St. Andrew's Home itself has been in existence for a number of years, and was selected by Dr. W. J. Fenton as an ideal place for the treatment of debilitated, anæmic, and under-developed children. The home stands just back from the beach, which is one of the safest in England, sloping almost imperceptibly to the sea, and leaving, except at actual high tide, a large expanse of firm sand covered for a considerable distance by only a few inches of water. Here the children can spend most of the day, returning to eat and sleep in shelters open entirely on one or more sides to the air. Clothing is reduced to a minimum, and what little is worn in winter is of the loosest and most hygienic pattern. In November, 1922, a hut of ten beds was erected, to which 37 of the most miserable and undersized children attending the Chelsea Tuberculosis Dispensary were sent during the past year. The results exceeded expectation. With an average stay of three and a half months the average gain in weight of these children was 8 lb. 3½ oz. (the greatest being 20 lb.) associated with a gain in height of 1 to 2½ inches. Naturally these results have not been reached without effort, and the success is rightly attributed in large part to the ceaseless coöperation of Dr. A. J. May and Miss Twining, medical officer and matron respectively of St. Andrew's Home, with officers of the Invalid Children's Aid Association, not forgetting the guard of the 10.15 train from Victoria. In its new and enlarged form the hut may prevent many of these so-called pre-tuberculous children from becoming the victims of tuberculous disease.

TREATMENT OF VARICOSE VEINS BY INTRAVENOUS INJECTION OF QUININE.

Although many ingenious operations have been devised for the relief or cure of varicose veins, few, if any, have circumvented the danger of thrombosis and embolism. There are, in fact, few large statistics of excisions of varicose veins in which thromboses and pulmonary embolism do not figure more or less conspicuously. In a review of this subject Dr. Henry Bardy,[1] of Helsingfors, gives an account of an incident which was singularly tragic. A young woman, looking the picture of vigorous health, consulted him for large but strictly limited and uncomplicated varicose veins. The case was one that seemed eminently suited for Babcock's operation, supplemented by excision of the great saphena vein. But when she was advised to undergo this operation she hesitated; her best friend had died of embolism as a sequel to it. She consented to it, however, when she was reassured by the statement that this danger could be avoided by strict rest in bed for a considerable time after the operation. The operation itself was perfectly successful, the wound healing without sepsis or other complications. She got up on the fifteenth day and fell dead on the floor. The necropsy showed embolism of the pulmonary artery following detachment of a thrombus from the stump of the great saphena vein. Having experienced another somewhat similar fatality among his 133 operations for varicose veins, Dr. Bardy has recently been exploring with his assistant, Dr. Ulfves, the possibilities of artificially provoking thrombi which would be firmer and more adherent to the walls of the veins in which they were first formed than the thrombi formed under ordinary conditions. They have found that the introduction of a solution of quinine into a vein not only hastens the rate of coagulation of the blood, but also effects changes in the walls of the vein favouring firm union between them and a blood-clot. Dissection of a vein, in which thrombosis had been artificially induced by an injection of quinine, showed that not only was the clot firmly attached to the vein, but that its wall was permeated by a blood-stained gelatinous substance. These investigations give support to the procedure advocated by Genevrier in 1922 in *Monde Médical*, No. 611. Genevrier's solution is: hydrochloride of quinine, 4; urethan, 2; distilled water, 30. The patient sits with legs hanging down, the field of operation having been disinfected with iodine. From 0·25 to 0·5 c.cm. of the solution is injected, an ordinary hypodermic syringe with a fine-pointed needle being used. It does not matter, and may, indeed, be advantageous, if a little of the solution fails to reach the lumen of the vein, and is deposited in its wall or in the immediate neighbourhood. The site of the puncture is closed with a little cotton-wool and collodium, and the injection is repeated about 8 cm. higher up the leg. Genevrier seldom injects more than a total of 4 c.cm. at one sitting. The resultant thrombosis is somewhat painful during the next few days, and it is advisable to defer the second series of injections for a week. Genevrier has given more than 4000 such injections without signs of embolism, and Dr. Bardy has given more than 500 injections to 26 patients without having to register a single accident. If further investigations should prove that the artificial quinine thrombus possesses sedentary and adhesive properties greatly in excess of those of the accidental thrombus, we may perhaps hope to see the operative treatment of varicose veins entering on a chapter less frequently punctuated by the tragedies of the fugitive thrombus.

VOCATIONAL CANCER.

We reported not long ago[1] a legal test case of vocational cancer in which the point at issue lay in whether "epitheliomatous ulceration" or "epithelioma of the scrotum" contracted in the course of a worker's employment as a mule-spinner was a disease for which compensation should be paid. The following two further cases of vocational cancer have since come before coroners' courts in the North of England, and out of one of them an important suggestion for the prevention of the disease has emerged. On April 21st at Middleton the county coroner, Mr. E. N. Molesworth, held an inquest into the cause of death of John William Fitton (53), who up to August last had been employed for about 18 years as a cotton spinner. Medical evidence by Dr. W. D. Findlay showed that in February last deceased suffered from an ulcer of the scrotum with secondary infection of the glands in the left groin. He was subsequently admitted into the Royal Infirmary, Manchester. Dr. Findlay expressed the view that the deceased's occupation was primarily responsible for his final illness—cancer of the scrotum. A verdict in accordance with the medical evidence was recorded. The Manchester city coroner, Mr. C. W. Surridge, on April 23rd concluded the inquest on John Allen (50), who died in the Crumpsall Institution on March 16th. The deceased had been employed for nearly 20 years in a chemical works at Weaste as a pitch-getter. Mr. Seal, H.M. Inspector of Factories, and Dr. S. A. Henry, medical inspector under the Factory Acts, attended the inquiry. In March deceased was certified to be suffering from cancer of the scrotum, which was attributed to the handling of pitch. As a pitch-getter Allen had to break up very hard pitch by driving in wedges with a heavy hammer, and also to place the larger pieces on lorries and shovel the smaller fragments. All this was done in the open air, and a certain amount of dust was produced by the breaking up of the pitch. The deceased had suffered from the epitheliomatous tumour for 18 months, and the inguinal glands were involved. The coroner returned a verdict that Allen had died from cancer due to his work in tar. Mr. Surridge, addressing the secretary of the company who employed Allen, said that they were not at present bound by law to have any medical examinations of their employees, adding he would like to ask if they were prepared, in view of this case, to take steps to have an examination. The secretary replied that they were, and that already a number of their men had been examined, and the company intimated that they were prepared to have regular periodical examination of their men in the hope of stopping such cases. The coroner said that this was a most praiseworthy attitude.

TREATMENT OF POTT'S DISEASE.

THE large statistics which have recently been published should enable us to form a fairly balanced opinion of the comparative merits of conservative and operative methods of treatment in Pott's disease. These methods, it would seem, are to be regarded rather as complementary than as competitive, and a recent paper by Dr. Henning Waldenström,[1] of Stockholm, lays stress on the wisdom of preparing for operative treatment by a prolonged course of immobilisation in plaster. Since he began to employ Albee's method about ten years ago, he has followed a procedure which he calls "osteosynthesis after gradual correction." Of its value in other hands he is unable to speak, for the simple reason that no one has hitherto adopted it in a large series of cases observed over a considerable time. But of its value in his own hands there can be doubt, and up to the end of 1922 he had treated 80 cases in this manner. The fate of all was ascertained in the spring of 1923, and it was found that none of the seven deaths could be traced to the operation. The treatment being particularly difficult in childhood, the patients were classified according as they were under or over the age of 15. There were 66 patients under this age, and in 58 of these 66 cases recovery was effected with excellent functional and cosmetic results. Before these results were, however, attained, the careers of many of the patients were chequered. In as many as 14 cases the tibial graft fractured, and in the seven cases in which the operation was repeated on this account ideal results were ultimately obtained. Several of these fractures were due to severe injuries such as a fall from a great height or a spill on ski, and it is evident that the Albee patient who would live the life of an athlete may sometimes find himself actually and metaphorically skating on thin ice. When a child has exhibited signs of kyphosis for half a year, Dr. Waldenström refuses to operate until it has been recumbent in a Lorenz plaster bed for a year, and he abides by this rule even if the kyphosis is completely corrected before the expiry of this time. In spite of this precaution he has found that the surgeon may be surprised by the continued extension of the disease, and if the child is less than 3 or 4 years old it is better to wait at least two years after the onset of the disease. Dr. Waldenström is as careful in his post-operative as in his pre-operative treatment, and the fact that he can claim complete correction of the kyphosis and restoration of normal functional capacity in 80 per cent. of all his cases is doubtless largely due to his post-operative measures, which include immobilisation for two to three months in a plaster bed, then the wearing for another two or three months of a plaster corset, and finally the wearing of a steel corset for a year or two.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE report for the year 1923 will be presented at the annual general meeting of the Society on May 7th. Since the last report 11 new members have been elected and 28 have been lost owing to death and resignation. The Society at the present time consists of one honorary, 152 life and 136 ordinary members, making a total of 289. The invested capital now stands at £147,650; in conformity with the by-laws only income may be used for the payment of grants and expenses. The income from investments during the year amounted to £4642, £313 10*s.* were received from subscriptions and donations; the working expenses were £350. During the year one widow died and one came on the funds; on Dec. 31st there were 51 widows and 6 orphans in receipt of grants. £4497 10*s.* were distributed in grants during the year. Two orphans during the past five years have received between them from the Brickwell Fund £575 to enable them to study for the medical profession; both qualified this year and are now holding house office in a London hospital. Membership of the Society is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. Relief is granted to the necessitous widows and orphans of deceased members of three years' standing and of life members. At the present time the widow of such member who has an income of not more than £125 a year receives a grant at an average rate of £50 per annum, paid half-yearly in advance, and each orphan, up to the age of 16, receives a grant of £40 per annum. An orphan, on attaining the age of 16, ceases to be eligible to receive grants from the ordinary funds. There are, however, two special funds from which grants can be made to orphans after the age of 16, and also special grants from £10 to £25 to widows. The annual subscription for a member who at the time of his election is under 40 years of age is 2 guineas, if over 40 but under 50, 3 guineas, and if over 50, 4 guineas.

TYPHOID FEVER SIMULATING ACUTE APPENDICITIS.

Dr. F. de Gironcoli,[1] of the Third Surgical Division of the Civil Hospital at Venice, who records an example in a girl aged 11, discusses the cases of typhoid fever with sudden onset which may simulate acute appendicitis. One of the first cases of the kind was published by Kirkebride in 1891, but Moizard, in 1899, is to be credited with having drawn special attention to the form of typhoid simulating appendicitis. After the appearance of Moizard's communication a series of cases of this kind were published in which the subsequent progress of the disease enabled one to exclude appendicitis. In other cases, as in that reported by Gironcoli, the persistence of severe local symptoms favoured the suspicion of appendicitis and was the cause of an operation being performed. In a large proportion of these cases the appendix was found to be normal, or the changes in it were not sufficient to account for the severity of the symptoms. In other cases, again, the appendix itself was found to be more or less normal, but changes were found in the neighbourhood which explained the pain and other symptoms, and enabled a diagnosis of typhoid fever to be made. Gironcoli's conclusions are as follows: (1) cases of typhoid fever may occur with a sudden onset simulating acute appendicitis; (2) the differential diagnosis between typhoid fever in the early stage and appendicitis is occasionally impossible; (3) when symptoms of acute appendicitis are present, even if typhoid fever is suspected, one should not wait longer than 48 hours before operating; (4) appendicectomy in the early stage of typhoid fever does not aggravate the course of the disease.

MEDICO-LEGAL IMPORTANCE OF BLOOD-GROUPS.

AT the recent meeting of the Medico-Legal Society Dr. G. Roche Lynch told the story of blood-groups from their first discovery in 1900 with a view to determining their importance, if any, from the medico-legal standpoint The relative numbers of these groups in the ordinary population are now fairly well known as well as the broad differences found between Europeans and Asiatics. These were given by L. and H. Hirschfeld [1] in 1919 as follows:—

Cases.	Groups.			
	I.	II.	III.	IV.
Europeans—				
Average of 4000 ..	4·70 ..	41·23 ..	12·14 ..	41·93
Asiatics—				
Average of 2500 ..	6·74 ..	21·84 ..	32·74 ..	38·68

Of the various theories advanced in explanation of these facts Dr. Lynch finds that of Dungern and Hirschfeld alone at all convincing; they postulate two agglutinogens and two agglutinins. The application of the test lies in two directions, (1) blood-stains, (2) paternity cases. In the case of a man charged with murder, it might be claimed by the prosecution that blood-stains found on him were from the victim, and by the defence that they were from himself; the group of the stain would in many instances enable one or other of these suggestions to be negatived. Tables by Dyke and others give the blood-groups of the offspring that might be produced by any combination of parents:—

Parents.	Offspring may be—	Cannot be—
I. and I. I. ,, II. I. ,, III. I. ,, IV. II. ,, III.	I., II., III., or IV.	—
II. ,, II. II. ,, IV.	II. or IV.	I. or III.
III. ,, III. III. ,, IV.	III. or IV.	I. or II.
IV. ,, IV.	IV.	I., II., or III.

It would seem to be possible to demonstrate from the blood-groups that a given child could not have been produced by some particular parents—e.g., a Group II. child could not have sprung from two Group IV. parents.

Dr. F. C. Martley, who followed Dr. Lynch, gave an account of the technique employed to determine to what group any person's blood belongs and the modifications necessary to apply when investigating a blood-stain. He first demonstrated the method ordinarily used to test a particular blood: a drop of II. serum and a drop of III. serum are placed at either end of a slide and a little of the blood is taken up on a platinum needle and mixed with each; agglutination can be readily seen with the naked eye in a few minutes; when it occurs in both drops the blood is of I. group, when in neither it is IV. group, and when in only one it belongs to the group of the serum where there is no agglutination. To test the titre of a blood serum the further step is taken of putting up drops of whole serum, half serum, quarter serum, one-eighth serum, and so on, up to about 1/250 serum; an equal volume of a 1 per cent. dilution of appropriate corpuscles is added to each, and the agglutinations noted under the low power of a microscope—they may extend nearly to the end of the series, or may only go down three or four places, the range varying greatly in different cases. As regards blood-stains, valuable work has been done by Schütze. The problem can be approached in two ways: (1) An extract of the stain can be used to agglutinate known corpuscles, or (2) the agglutinating power of a known serum may be varied by treating it with unknown stain. The first is often difficult to demonstrate, but when a blood-stain on a garment is cut up into fine fragments, and incubated in a sealed glass tube with a minimum of distilled water, the fluid obtained therefrom, when filtered free of any particulate matter, generally agglutinates appropriate corpuscles when the preparation is kept overnight in a moist chamber. The second method depends on the agglutinating power of a serum being finite; for instance, when a IV. serum which agglutinates II. and III. corpuscles is treated with II. corpuscles, it can still agglutinate III. corpuscles as before, but its action on II. corpuscles is lessened as shown by the titre that gives agglutination, or abolished entirely. In practice the blood-stain is cut up as in the previous experiment, but put up with known IV. serum instead of distilled water; after incubation as before the serum is drawn off and filtered and its power tested against known corpuscles. In the case of a IV. blood-stain no impairment of agglutinating power should be found, but in the case of the other groups it can generally be detected; for instance, if the titre of the treated IV. serum was unchanged for III. corpuscles, but very markedly diminished for II. corpuscles, it would be shown that the stain in question was of a II. blood. Negative evidence alone, as Dr. Martley was careful to point out, may be fallacious owing to the blood-stain having become inert from age or otherwise or from having been too small. When definite positive evidence was obtained and confirmed, in no case had it led him astray.

THE EFFECTS OF ULTRA-VIOLET RAYS ON THE PARATHYROIDS AND CALCIUM METABOLISM.

THE biophysics of the ultra-violet rays is a territory in which many fields of research still lie fallow, and some useful spade-work has recently been done by two investigators, J. H. B. Grant and Frederick L. Gates, of the Rockefeller Institute,[1] which breaks fresh ground on the effects of the rays on certain endocrine glands. These workers exposed normal rabbits to the quartz-mercury arc lamp daily for periods of three to seven weeks and observed at autopsy the weight of certain endocrine glands in relation to the body-weight of the animal. Many controls were required because of individual and (in particular) seasonal variations in the gland body-weight ratio. Light-coloured or albino male rabbits, with ears shaved and backs clipped, were exposed to the unfiltered radiations of a quartz-mercury arc lamp for 30 minutes daily at a distance of 1 metre. The rays caused a marked erythema with some desquamation, followed by moderate pigmentation. At the expiration of the chosen period the animals were etherised and bled from the aorta. The weights of the several endocrine glands and the testes were recorded in milligrammes per kilogramme of body-weight. The changes in weight, per cent., compared with the normal controls are recorded. Leaving aside the somewhat fluctuating results in the other glands, the authors direct special attention to the considerable hypertrophy of the parathyroids. The percentage increase in weight from normal in these glands was at 3 weeks, 34·6; at 4 weeks, 51·1; at 5 weeks, 31·9; at 6 weeks, 27·7; and at 7 weeks, 14·1, the increase being most marked especially during the earlier periods of the experiment. The later decrease in weight the authors attribute to the protection afforded the rabbits by pigmentation. The increases in weight were due to a true hyperplasia of the parenchymatous tissue, as shown by microscopic examination. The examination of the calcium metabolism after exposure to the rays gave interesting results. The experiments showed changes in absorption and excretion of calcium and in the calcium level of the blood. It was found that the average blood calcium concentrations for the last three groups at autopsy—i.e., at 5, 6, and 7 weeks—were 12·7, 12·9, and 12·6 mg. per 100 c.cm. of serum as compared with an average of 11·9 mg. for 60 normal control rabbits. In another set of experiments rabbits were given increased exposures of ultra-violet light daily over a period of four weeks. These animals showed a relative increase of 32 per cent. in the parathyroid weight over the normal figures, and the blood calcium concentration rose from 11·9 mg. per 100 c.cm. of serum before exposure, to 12·2 mg. on the twelfth day, 13·5 mg. on the twenty-second day, and 12·9 mg. at autopsy. The normal relationship of the parathyroids to calcium metabolism is well established, but these experiments serve to relate the effect of ultra-violet light on calcium metabolism to the parathyroid glands. Whether the light acts primarily on the absorption and excretion of calcium and causes a rise of the blood calcium which results in a hypertrophy of the parathyroid gland, or primarily affects the glands themselves, remains to be determined.

VIRULENT SMALL-POX IN ONTARIO.

CONSIDERABLE interest attaches to the report of Dr. John W. S. McCullough, the chief officer of health of Ontario, on a recent epidemic of smallpox in the "border cities" of Ontario. A small epidemic of small-pox was present in Detroit in the early part of this year and, as was to be expected, a few cases developed in the neighbouring cities of Canada. These cases, however, were all of a mild character and occasioned no alarm, but about the middle of February an epidemic of malignant small-pox broke out in Windsor, Ont., following the death of a man suffering from an irregular type of the disease. This man, as the report states, was attended during his illness by several medical men of the highest reputation, none of whom believed that the patient was suffering from a communicable disease. During his illness the man was visited by many friends and relatives, and it was only when cases occurred subsequently in persons who had been in contact with him that the diagnosis of small-pox was definitely made. These cases were all of a particularly virulent and irregular type, and up to the early part of March the total number of cases which could be traced apparently to this source reached 42. Dr. McCullough states that it has not been possible so far to ascertain the source of infection of the original cases, but, whatever the source, the disease has been of a virulent form with a high mortality. In his report he brings out several points of importance in connexion with the epidemic. In the first place, the available evidence points to the first unrecognised case being one of sudden increase of virulence in the type of disease, and this Dr. McCullough believes was due to the fact that the person infected had never been vaccinated. Other points were the irregular character of the prodromal symptoms and of the rash. He divides the cases into three distinct types: (*a*) mild cases with history of an old successful vaccination over 12 years ago, also an occasional unvaccinated case who had been infected in Detroit; (*b*) severe semi-confluent and confluent cases which occurred solely in unvaccinated persons; and (*c*) hæmorrhagic cases which also occurred solely in unvaccinated persons and were all fatal. These latter cases, he states, were very difficult to diagnose even with the information that an epidemic of severe small-pox was present, and some of them showed a typical "lobster rash," as mentioned by Dr. Claude B. Ker in his book on infectious diseases. Dr. McCullough draws as his conclusion from the epidemic that the value of vaccination as a means of prevention has been proved, as it never was before, in an epidemic more severe than anything which Canada has seen since the Montreal epidemic of 1885. The deaths among unvaccinated persons suffering from the disease ran to 50 per cent. During the last week in February roughly two-thirds of the exposed population, or 50,000 people, were vaccinated. Dr. McCullough remarks with justifiable pride that there has probably never been a city in Canada which has been able to accomplish such a feat without the use of compulsory methods. The severity of the disease and the confidence of the people in their local health authorities made this possible. The value of the by-law providing for vaccination of children on entering school was shown in this epidemic by the absence of spread among the school population.

THE USE OF ARSPHENAMIN AFTER EXPOSURE TO SYPHILIS.

IN a review of the literature with a record of his own experience of the use of arsphenamin or salvarsan after exposure to syphilis, Dr. David L. Simon,[1] of Pittsburgh, abstains from employing the term "prophylaxis," as the question as to whether it is a prophylactic or curative measure is open to discussion. Pardoe-Castello, for example, with whom Dr. Simon is inclined to agree, maintains that it is a curative procedure in that it prevents the appearance of symptoms by curing the disease in the incubation period. The term "prophylaxis" is more applicable to modifications of Metchnikoff's method in which calomel or other spirochæticides are used directly after exposure to destroy the organisms in situ before they enter the blood stream. Local prophylaxis, however, is insufficient if used more than 12 hours after exposure, and it is in this group of cases that treatment by arsphenamin is most likely to be of value. Dr. Simon, who has employed his treatment for the last four years, confines it to persons who present themselves within 72 hours after exposure. The application of the method after this time is inadvisable, as there is a risk of giving insufficient treatment to a case in which intensive therapy is required. The cases treated had no previous history or evidence of syphilis, and all gave a negative Wassermann reaction. In most of the cases signs of active syphilis were present in the partner. The method consisted in the injection, every other day for three doses, of 0·3 g. neoarsphenamin dissolved in 10 c.cm. of distilled water. The Wassermann reaction was examined two weeks after the last dose and then at monthly intervals for four months. In the four cases which Dr. Simon records the Wassermann reaction remained negative, and no clinical evidence of syphilis was detected in persons so treated who had been kept under observation for periods ranging from four months to two years.

THE annual oration of the Medical Society of London will be given by Mr. Wilfred Trotter on Monday, May 5th, at 9 P.M., the subject being On Certain Minor Injuries of the Brain. The President, Dr. Herbert R. Spencer, will receive members and their guests at 8.30 P.M., and the oration will be followed by a conversazione.

THE fifth Maudsley Lecture of the Medico-Psychological Association of Great Britain and Ireland will be delivered at 3 P.M. on May 22nd at the Royal Society of Medicine, by Dr. John Carswell, Commissioner of the Scottish Board of Control. The title of the lecture will be "Some Sociological Considerations Bearing upon the Occurrence, Prevention, and Treatment of Mental Disorders."

THE exhibition of works of art by medical men, which is to be held in the Marcus Beck Room, at the Royal Society of Medicine, will be open from May 26th to June 14th. It is confined to works by Fellows and Members of the Society, and as the new movement is frankly an experiment, the space is very limited. The modest character was decided upon at the outset by those who, with the President of the Society, Sir William Hale-White, promoted the idea. Dr. Cuthbert Lockyer is acting as hon. secretary, and the selection and hanging will be supervised by Mr. Sydney Kendrick.

---

[1] Urological and Cutaneous Review, April, 1924.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXIX.—THE TREATMENT OF ACUTE AND CHRONIC PAIN.

MORPHIA is immeasurably the best anodyne drug we possess; if there were no drawbacks in its use it would be unnecessary to discuss other anodynes. However, since its disadvantages are well known and dreaded, the use of opium preparations is usually postponed as long as possible, and consideration of the efficacy in relieving pain of less dangerous drugs becomes essential. In selecting an anodyne drug the following points arise:—

(*a*) *The Point at which the Drug Acts.*—Aconite, belladonna, and cocaine act peripherally; cocaine, hypodermically, may bring relief, but only when the injection is made at the point of lesion. Morphia acts only on certain pain centres in the brain, and is therefore wasted in the time-honoured lead and opium lotion and in laudanum fomentations; rectal morphia suppositories are efficacious only so far as the morphia is absorbed and carried to the brain. The synthetic or coal-tar preparations, aspirin, phenacetin, antipyrin, and the like also act centrally. Counter-irritation, whereby the perception of pain at one point is distracted by irritation of another spot on the same nerve exchange must not be neglected.

(*b*) *Habituation and the Limits of Susceptibility.*—Unlike morphia, the synthetic remedies need not be increased to maintain a constant effect on the body. On the other hand, while the dose of morphine may be increased till the most severe pain disappears, there is a level of pain beyond the effective action of any of the other drugs. Headaches and rheumatic pains frequently yield completely to the synthetic anodynes; cancer pains are not so easily subdued, while inflammatory and ulcer pains may hardly be affected at all.

(*c*) *Habit Formation.*—Some drugs, as opium, cocaine, alcohol, produce a craving for more, with active discomfort when they are discontinued, and a loss of moral stamina. Coal-tar derivatives have no such effect.

(*d*) *Influence on Other Systems.*—Even in small doses morphia affects the respiratory centre, sometimes beneficially, as where it depresses needless cough, sometimes harmfully, as when phlegm resting in the bronchi fails to excite the clearing reflex. The fear that morphia in kidney disease may lead to cumulative retention is unfounded, for this drug is mainly excreted by the bowel, and may indeed be a most useful means of allaying discomfort in the last conscious days of a dying uræmic patient. The heart is not adversely affected by morphia, and advanced heart disease is no contra-indication to its use. On the other hand, constipation is a troublesome symptom in nearly all those who take morphia for a long period. On the whole, we are apt to fear the secondary effects of morphia too much rather than too little, and to forget that large doses of the synthetic products may cause sweating, rashes, and sometimes cyanosis from methæmoglobin formation. It should be remembered that when we relieve pain we not only make the patient more happy, but also reserve his strength and increase his resisting power. Pneumonia is a disease which lends itself to anodyne treatment.

Soporifics and Anodynes.

The centres governing sleep and pain being separate in the brain, we shall fail if, when pain is the cause of sleeplessness, we attempt to induce sleep with ordinary hypnotics. Morphia acts on both centres, but its anodyne comes before its soporific action; in fact, with the relief of pain the patient may become bright rather than drowsy. The coal-tar anodyne drugs are not directly soporific, but any relief of pain is likely to allow sleep to a normally tired person. The soporifics as sulphonal, chloral, and veronal are useless for pain but form valuable adjuncts to the true anodyne drugs, since they induce sleep as soon as pain is subdued. Other drugs hold an intermediate place. Luminal, sometimes used as a hypnotic, may give enough analgesia to put to sleep a patient even though he has pain. Dr. R. B. Wild has observed that a patient suffering from cancer wakes from a morphine sleep free from pain, which will only come on later; one who sleeps as the result of luminal wakes with his pain at full force.

The *duration of relief* varies with different drugs. Opium for some reason has the advantage even over its active principle morphia, and its effects certainly long outlast those of the synthetic drugs.

Morphia in Acute and Chronic Cases.

Though morphia is the best pain-killer we possess, owing to the fear of "habit" it is inapplicable in minor maladies and is inadvisable in major non-fatal illnesses likely to be protracted. It is justified when the illness is acute and painful, but likely to be short, or where a prolonged illness is leading to a certainly fatal termination.

In *acute cases* treatment by morphia for severe abdominal pain needs a rare discrimination, for it may mask diagnostic symptoms on the one hand, and on the other it may help by preventing spread of infection; while if it turns out there is no surgical lesion, unnecessary pain where morphia has been withheld is regrettable. In pneumonia another problem arises. Does the opium which eases the pain and allows sleep dull the respiratory centre sufficiently to cause risk? I think it does not, and I believe it to be one of the most efficient remedies in the first week of pneumonia, leaving the patient more fit to fight through when the crisis is at hand.

In *prolonged fatal cases*, as inoperable cancer, the question is rather one of the limit of size of dose to which the patient can attain. From the medicinal point of view there is no limit, though there are mechanical and financial disadvantages in continuous increase of dose. It is wise to withhold the drug within sufficient limits to keep an easily manipulated remedy in hand.

The Sequence of Drugs in Prolonged Fatal Cases.

The plan I aim at is to start with some coal-tar products, gradually reinforcing these by some morphine preparation. The duration of relief afforded by the synthetic drugs alone is very short and is prolonged by morphia in increasing doses. The synthetic drugs cannot be increased to any great extent since toxic symptoms arise, nor can they replace each other. It is well to keep the patient on coal-tar derivatives longer than is usually done. Of these, aspirin has become almost too well known to the lay public. Its high anodyne property combined with its low toxicity places it among the first of its class. But even aspirin may cause toxic symptoms, especially given with alkalies, as when it is washed down with soda water. Phenacetin, though weaker, acts wonderfully well in some cases. Antipyrin has the advantage of being soluble in water and can be given in mixture. A disadvantage of all these drugs when more than 15 g. is given is that profuse sweating may be caused and sometimes collapse. Blueness must be looked for if they are pressed. Fortunately this destruction of hæmoglobin is rarely serious, and even when blueness appears one may continue the drugs if caution is used. Powders of these preparations may be combined with powdered opium or Dover's powder, or pills and tablets of the two drugs taken together. Another useful combination is that of opium with a soporific drug, which, though useless alone, materially diminishes the amount of opium necessary to produce sleep—for example, a mixture containing t. opii, ℳ xv., pot. brom., gr. xv., and chloral hyd., gr. xv.

Counter-irritation in one form or another may be useful Painting with iodine over the chest, blisters over the head or body may be useful for a time. Spirit of cajuput in full doses may give great relief in a stomach cancer.

Alcohol has a definite anodyne action in doses not great enough to cause drowsiness or excitement, and may be continued far into the illness. Patients generally favour whisky and champagne; the possibility of the alcohol habit must not be forgotten in non-fatal cases.

Opium versus Morphia.

There are differences, largely manipulative and mechanical but also therapeutic, between opium and morphia. Morphia is more expensive. That it lends itself to hypodermic injection is a two-edged weapon; the patient is less likely to take to this method of medication himself, but if he does acquire the habit it is more likely to become confirmed. Morphia, hypodermically, acts quickly, and when one is attempting to keep the dose down, rapidity of action is important, for the patient is less likely to clamour for his drug in anticipation if he knows he can get easy relief when he really needs it. But it is not in every household that one can leave a hypodermic syringe to be used by a layman. When both are given by the alimentary canal, opium acts more slowly than morphia, but for a longer time. It is interesting to note that tincture of opium, the repeated dose of which in the British Pharmacopœia is ♏ v. to xv., is of the same strength of morphia (1 per cent.) as the morphine solutions of which the dose is ♏ x. to lx. On the whole, opium has the wider range, and it is wise to keep morphia in reserve unless circumstances specially favour its use. Of the solid preparations of opium, Dover's powder is especially useful in febrile conditions as the ipecacuanha reinforces the slight sudorific action of the opium, but sometimes the emetine causes nausea. Soap pill, which is used mainly for its analgesic action, has, like the compound ipecacuanha preparations, the advantage of suppression of the word opium. Omnopon, dose $\frac{1}{6}$–$\frac{1}{3}$ gr., is said to contain all the active constituents of opium without its resins and inert bodies; it is quite effective and useful in its tablet form, and may not upset the stomach as much as does opium. Of the fluid preparations, nepenthe and Battley's liquor sedativus are more pleasant than the official tincture, and given in slightly larger doses are as effective. The pharmacopœial liquid extract of opium, for which the opium is extracted with water, has the advantage over the tincture of not containing the resinous bodies which disagree with the stomach; it is an official preparation which deserves much more use than it gets. Opium in some form is irreplaceable in certain cases of pain, especially for malignant disease. Most medical men will agree with Dr. Robert Hutchison's recent words, "When our time comes . . . . I hope it may be your fate and mine to find ourselves in the hands of a doctor who is not afraid to use morphine."

BRITISH EMPIRE EXHIBITION, WEMBLEY:

HEALTH IN THE TROPICS.

I.

"THIS Exhibition . . . stands for the coördination of our scientific knowledge and a common effort to overcome disease . . . in many parts of the Empire." With these words the King referred to the share that medical men and women have in the problems of Empire when he opened the British Empire Exhibition on April 23rd, 1924.

The quotation "Good wine needs no bush" is misleading when used as a proverb; where the wine is applauded publicly as good it may not need the advertisement of the Bacchic bough, but as long as its virtues are ill-recognised, every opportunity for displaying them should be taken. And as was pointed out in these columns recently, the cause of disease prevention within the far-flung bounds of our Empire still needs much effort for the enlistment of public sympathy. Unless the public understand and coöperate, the medical profession cannot succeed in the task of making it possible for native and white man alike to live and move and have their being in each and all of our dominions unmolested by the terrible scourges of endemic and epidemic disease. Vast areas of our Empire, rich in promise, are as yet little, if at all, opened up for the service and well-being of mankind owing to the heavy toll which disease takes of those who would labour there.

Apart from the actual cure or prevention of disease, we have in many of our dominions the question of the means whereby it may be possible to bring medical aid within the reach of those thousands of men and women who are to all intents and purposes isolated amid vast tracts of unpopulated country. Here the health and well-being of countless British subjects depend as much on the engineer as on the medical man, and yet unless the medical man first make the country free from disease how shall it be possible for the engineer to construct railways? Or how shall the advent of the trader and settler, in sufficient numbers, render possible the provision of hospitals and all that is necessary for the establishment of self-supporting medical services? Government and charitable aid may do much, or even all, that is necessary for the clearing of a given tract of country from some specific disease, but it is the advent of a self-supporting population in the wake of the scientist which renders possible a general medical and surgical service, such as is indispensable for the well-being of a community. The provision of an adequate health service rests principally with those bodies, governments, local authorities, and commercial undertakings on whom rests the responsibility of voting the necessary money. This money may be voted either because there exists a brotherly desire to help others, or because the body concerned considers, with Celsus, that "health is wealth"—the two motives are generally concurrent. The medical services overseas would not have been starved for so long if people had, ere now, realised to the full the enormous increase of wealth that is possible if only the immediate sphere of their operations could be made healthy. The overseas officials and others would have their lives made much more enjoyable if in the countries where their work lay their wives and families could live wholesomely; then the establishment of a permanent community would be fully beneficial to the locality and the Empire.

The British Empire Exhibition will have served a great purpose if it brings home to the public the immense importance and need of proper medical and sanitary services, even if looked at merely from the motive of greater return for the effort and wealth that are expended in the various parts of our dominions. A brief survey of the exhibits in the Tropical Health Section of the exhibition appeared in these columns recently, and these are so much to the point and their arrangement so good that the only thing that need be said further in this connexion is that the lay public, and especially those with interests abroad, should be exhorted to go and see for themselves some at least of the factors which enable us to present health reports from the colonies as satisfactory as those which we publish regularly in THE LANCET. These reports make no pretence of being complete, but they are sufficiently representative to enable the reader to form the bright hopes of victory in the various great fights against disease.
